Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

Optimizing Requests

How to:
Optimize Requests

Example:
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

Reference:
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

```
SQL SQLMAC SET {OPTIMIZATION|SQLJOIN} setting
```

where:

- `SQLMAC`
  
  Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.
SQLJOIN

Is a synonym for OPTIMIZATION.

setting

Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.

Both OPTIMIZATION settings produce the same report.

Example: SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```sql
SQL SQLMAC SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID, T1.LN, T1.DPT, T1.CSAL, T1.OJT
  FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
  FOR FETCH ONLY;

Adapter Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS 1287
**Example:** **SQL Requests Passed to the RDBMS With Optimization ON**

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLMAC SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
    SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
    IF DEPARTMENT EQ 'MIS'
    END

In a trace operation, you will see the following output:

AGGREGATION DONE ...
    SELECT T2.EID,T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
    FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
    WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
    GROUP BY T2.EID,T1.LN
    ORDER BY T2.EID,T1.LN;
```

**Reference:** **SQL Generation in Optimization Examples**

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:**
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.
**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax:**

**How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields**

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLMAC SET OPTIFTHENELSE {ON | OFF}
```

where:

**SQLMAC**

Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Enables IF-THEN-ELSE optimization. This is the default.

**OFF**

Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:**

**Using IF-THEN_ELSE Optimization Without Aggregation**

Consider the following request:

```sql
SQL SQLMAC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```
The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN',T1.'FN',T1.'DPT' FROM USER1.'EMPINFO' T1
  WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' '))
    AND (T1.'DPT' = 'MIS'))));
```

**Example: Using IF-THEN_ELSE Optimization With Aggregation**

Consider the following request:

```sql
SQL SQLMAC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
  ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
  WHERE (((T1.'LN' = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
  WHERE (((NOT (T1.'LN' = 'SMITH'))) AND (T1.'LN' = 'JONES')));
```

**Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False**

```sql
SQL SQLMAC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
  IF DEF3 EQ 2
END
```
Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```

**Reference:** SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  
  ```
  X=X+1;
  ```
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

  **Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX and MIN prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

  **Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Specifying Block Size for Retrieval Processing

**How to:**

- Specify the Block Size for Array Retrieval
- Specify the Block Size for Insert Processing
- Suppress the Bulk Insert API

The Adapter for Microsoft Access supports array retrieval from result sets produced by executing SELECT queries or stored procedures. This technique substantially reduces network traffic and CPU utilization.

Using high values increases the efficiency of requests involving many rows, at the cost of higher virtual storage requirements. A value higher than 100 is not recommended because the increased efficiency it would provide is generally negligible.

**Tip:** You can change this setting manually or from the Web Console by clicking Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the right-click menu. The Change Settings pane opens.

**Syntax:**  
**How to Specify the Block Size for Array Retrieval**

The block size for a SELECT request applies to TABLE FILE requests, MODIFY requests, MATCH requests, and DIRECT SQL SELECT statements.

```plaintext
ENGINE SQLMAC SET FETCHSIZE n
```

where:

- `SQLMAC` indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
- `n` is the number of rows to be retrieved at once using array retrieval techniques. Accepted values are 1 to 5000. The default varies by adapter. If the result set contains a column that has to be processed as a CLOB or a BLOB, the FETCHSIZE value used for that result set is 1.

**Syntax:**  
**How to Specify the Block Size for Insert Processing**

In combination with LOADONLY, the block size for an INSERT applies to MODIFY INCLUDE requests. INSERTSIZE is also supported for parameterized DIRECT SQL INSERT statements.

```plaintext
ENGINE SQLMAC SET INSERTSIZE n
```
where:

**SQLMAC**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**n**
Is the number of rows to be inserted using array insert techniques. Accepted values are 1 to 5000. 1 is the default value. If the result set contains a column that has to be processed as a BLOB, the INSERTSIZE value used for that result set is 1.

**Syntax:**  How to Suppress the Bulk Insert API

```plaintext
ENGINE SQLMAC SET FASTLOAD [ON | OFF]
```

where:

**SQLMAC**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**
Uses the Bulk Insert API. ON is the default.

**OFF**
Suppresses the use of the Bulk Insert API.
Using the Adapter for Microsoft SQL Server

The Adapter for Microsoft® SQL Server® allows applications to access Microsoft SQL Server data sources. The adapter converts data or application requests into native Microsoft SQL Server statements and returns optimized answer sets to the requesting program.

**Topics:**
- Preparing the Microsoft SQL Server Environment
- Configuring the Adapter for Microsoft SQL Server
- Managing Microsoft SQL Server Metadata
- Reporting Against a Microsoft SQL Server Stored Procedure
- Customizing the Microsoft SQL Server Environment
- Optimization Settings
- Calling a Microsoft SQL Server Stored Procedure Using SQL Passthru
- Microsoft SQL Server Compatibility With ODBC
Preparing the Microsoft SQL Server Environment

In this section:
Accessing Microsoft SQL Server Remotely
XA Support

How to:
Set Up the Environment on Windows
Set Up the Environment on UNIX

In order to take full advantage of the features available through the Adapter for Microsoft SQL Server 2005, we strongly recommend using MS SQL Server 2005 with Service Pack 1 (2005.90.2047) or higher. To determine which version of MS SQL Server you are using, please refer to the following article: http://support.microsoft.com/kb/321185.

You can set up the Microsoft SQL Server Environment on Windows and UNIX.

Procedure: How to Set Up the Environment on Windows

The Microsoft SQL Server environment is set up during the installation of the Microsoft SQL Server, Client, and MDAC software.

No additional setup steps are required.

Procedure: How to Set Up the Environment on UNIX

Identify the location of the Microsoft SQL Server JDBC Driver files using the environment variable $CLASSPATH. For example, to set the location of the JDBC Driver files to /usr/driver_files, specify:

CLASSPATH=/usr/driver_files
export CLASSPATH

Identify the installation directory of the Java Development Kit using the environment variable $JDK_HOME. For example, if you want to set the location of the Java Development Kit to /usr/java, specify:

JDK_HOME=/usr/java
export JDK_HOME

Identify the installation directory of the Java Virtual Machine using the environment variable $LD_LIBRARY_PATH. For example, if you want to set the location of the java virtual machine to /usr/j2sdk1.4.2_01/jre/lib/i386/server, specify:

LD_LIBRARY_PATH=/usr/j2sdk1.4.2_01/jre/lib/i386/server
export LD_LIBRARY_PATH
**Note:** If the server is running with security on, the LD_LIBRARY_PATH variable is ignored. In this case, you must use IBI_LIBPATH.

**Accessing Microsoft SQL Server Remotely**

You can access Microsoft SQL Server on a remote node. To access Microsoft SQL Server remotely, you must:

- Locally install the latest version of Microsoft SQL Server Native Client.
- Know the name of the remote Microsoft SQL Server instance.

All Microsoft SQL Servers installed are defined by using a unique NetBEUI name. The server can access any Microsoft SQL Server on the network, provided you define a valid user ID and password, as well as the name of the Microsoft SQL Server instance. You can define these parameters in either the server global profile or a user profile.

**XA Support**

Read/write applications accessing Microsoft SQL Server data sources are able to execute transactions managed in XA-compliant mode.

To activate the XA Transaction Management feature, the server has to be configured in Transaction Coordination Mode, using the Web Console configuration functions. Using Transaction Coordination Mode guarantees the integrity of data modification on all of the involved DBMSs and protects part of the data modifications from being committed on one DBMS and terminated on another.

For complete documentation on XA compliance, see [XA Support on page 2757](#).

**Configuring the Adapter for Microsoft SQL Server**

**In this section:**
- Declaring Connection Attributes
- Overriding the Default Connection
- Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Declaring Connection Attributes

How to:
- Declare Connection Attributes
- Declare Connection Attributes Manually on Windows
- Declare Connection Attributes Manually on UNIX and z/OS

Example:
- Declaring Connection Attributes on Windows
- Declaring Connection Attributes on UNIX and z/OS

Reference:
- Connection Attributes for Microsoft SQL Server

In order to connect to a Microsoft SQL Server database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTIONATTRIBUTES command.

You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one Microsoft SQL Server databases by including multiple SET CONNECTIONATTRIBUTES commands. The actual connection to the Microsoft SQL Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTIONATTRIBUTES commands:

- The connection named in the first SET CONNECTIONATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTIONATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTIONATTRIBUTES command.
Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   or
   From the Data Management Console, expand the Adapters folder.
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for Microsoft SQL Server

The MS SQL Server adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Server (Windows only)

Name of the machine where Microsoft SQL Server is running. If that machine has more than one instance of Microsoft SQL Server installed, provide the server name and the instance name as follows: server\instance.

The server connection attribute will allow users to choose from the list of MS SQL Servers visible within the local network using the SQL Native Client Enumerator.

Please note that due to limitations of the SQL Native Client Enumerator, local network settings and MS SQL Server settings, it is possible that not all operational servers will be visible. If the name of the server you wish to target does not appear, you can enter it manually.
Configuring the Adapter for Microsoft SQL Server

**URL (UNIX, IBM i, and z/OS only)**

Enter the location URL for the Microsoft SQL Server data source.

**Security**

There are three methods by which a user can be authenticated when connecting to a Microsoft SQL Server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to Microsoft SQL Server, at connection time, for authentication as a standard login.
  
  This option requires that SQL Server security be set to SQL Server and Windows (for Windows), or else to SQL Server and UNIX.

- **Password Passthru.** *(Windows only)* The user ID and password received from the client application are passed to Microsoft SQL Server, at connection time, for authentication as a standard login.
  
  This option requires that SQL Server security be set to: SQL Server and Windows.

- **Trusted.** The adapter connects to Microsoft SQL Server as an operating system login using the credentials of the operating system user impersonated by the server data access agent.
  
  This option works with either of the SQL Server security settings.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**Default Database (Windows only)**

Name of the default database for the connection. This value is used when a data object is not qualified with the database name.

This parameter is optional. If not specified, it defaults to the database associated with the authorization ID.

**Driver name (UNIX, IBM i, and z/OS only)**

Name for the Microsoft JDBC driver.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.
If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:**

**How to Declare Connection Attributes Manually on Windows**

**Explicit authentication.** The user ID and password are explicitly specified for each connection and passed to Microsoft SQL Server, at connection time, for authentication.

ENGINE SQLMSS SET CONNECTION_ATTRIBUTES [connection]
server/userid,password [;dbname][;provider_string]

**Password passthru authentication.** The user ID and password are explicitly specified for each connection and passed to Microsoft SQL Server, at connection time, for authentication.

ENGINE SQLMSS SET CONNECTION_ATTRIBUTES [connection]
server/;dbname][;provider_string]

**Trusted authentication.** The adapter connects to Microsoft SQL Server as a Windows login using the credentials of the Windows user impersonated by the server data access agent.

ENGINE SQLMSS SET CONNECTION_ATTRIBUTES [connection]
server/;dbname][;provider_string]

where:

**SQLMSS**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**

Is a logical name (or a data source name) used to identify this particular set of attributes. If you plan to have only one connection to Microsoft SQL Server, this parameter is optional. If not specified, the local database server serves as the default connection.

**server**

Is the name of the machine where Microsoft SQL Server is running. If that machine has more than one instance of Microsoft SQL Server installed, provide the server name and instance as follows: server\instance.

When specifying the server name and the instance name, we recommend that you enclose the value in single quotation marks (').

**userid**

Is the primary authorization ID by which you are known to Microsoft SQL Server.
password
Is the password associated with the primary authorization ID.

dbname
Is the name of the Microsoft SQL Server database used for this connection. The database name, including path, must be enclosed in single quotation marks.

provider_string
Is the Microsoft SQL Server provider string used to specify additional connection options, such as the name of the network library. Note that this parameter must be preceded by a colon and enclosed in single quotation marks. This parameter is optional.

**Note:** Enclose values that contain special characters in single quotation marks. If a value contains a single quotation mark, this quotation mark must be preceded by another single quotation mark, resulting in two single quotation marks in succession. For example, to specify the user ID Mary O’Brien, which contains both a blank and a single quotation mark, enter: ‘Mary O’ ‘Brien’.

**Example:** **Declaring Connection Attributes on Windows**

The following SET CONNECTION_ATTRIBUTES command allow the application to access the Microsoft SQL Server database server named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```sql
ENGINE SQLMSS SET CONNECTION_ATTRIBUTES SAMPLESERVER/MYUSER,PASS
```

The following SET CONNECTION_ATTRIBUTES command connects to the Microsoft SQL Server database server named SAMPLESERVER using Password Passthru authentication:

```sql
ENGINE SQLMSS SET CONNECTION_ATTRIBUTES SAMPLESERVER/
```

The following SET CONNECTION_ATTRIBUTES command connects to a local Microsoft SQL Server database server using operating system authentication:

```sql
ENGINE SQLMSS SET CONNECTION_ATTRIBUTES /,
```

**Syntax:** **How to Declare Connection Attributes Manually on UNIX and z/OS**

```sql
ENGINE SQLMSS SET CONNECTION_ATTRIBUTES CON1 'URL'/userid,password
```

where:

**SQLMSS**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
CON1
  Is the connection name.

URL
  Is the URL to the location of the data source.

userid
  Is the primary authorization ID by which you are known to the target database.

password
  Is the password associated with the primary authorization ID.

**Example:** Declaring Connection Attributes on UNIX and z/OS

The following SET CONNECTION_ATTRIBUTES command specifies using the Microsoft JDBC Driver.

```sql
ENGINE SQLMSS SET JDBCDRIVERNAME
  com.microsoft.jdbc.sqlserver.SQLServerDriver
```

The following SET CONNECTION_ATTRIBUTES command connects to a myServer using the Microsoft SQL Server JDBC Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```sql
ENGINE SQLMSS SET CONNECTION_ATTRIBUTES CON1
  'jdbc:microsoft:sqlserver://myServer:1433'MYUSER,PASS
```

Overriding the Default Connection

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:** How to Change the Default Connection

```sql
ENGINE SQLMSS SET DEFAULT_CONNECTION connection
```
where:

SQLMSS
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

collection
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

FOC1671, Command out of sequence

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  FOC1671, Command out of sequence.

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

ENGINE SQLMSS SET DEFAULT_CONNECTION SAMPLENAME

Controlling the Connection Scope

How to:
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

ENGINE SQLMSS SET AUTODISCONNECT ON {FIN | COMMAND | COMMIT}

where:

SQLMSS
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
FIN
Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMAND
Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

COMMIT
Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Microsoft SQL Server Metadata

In this section:
- Creating Synonyms
- Microsoft SQL Server Data Type Support
- Controlling the Mapping of Large Character Data Types
- Controlling the Mapping of Variable-Length Data Types
- Enabling National Language Support
- Trailing Blanks in SQL Expressions
- Changing the Precision and Scale of Numeric Columns
- Support of Read-Only Fields

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Microsoft SQL Server data types.
Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Sample Generated Synonym

**Reference:**
Synonym Creation Parameters for Microsoft SQL Server
Mapping Microsoft SQL Table Comments Into a Synonym
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each Microsoft SQL Server table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

The adapter supports the creation of metadata for certain types of MS SQL Native Synonyms. This feature is only available for Microsoft SQL Server versions 2005 and higher.

You can create metadata for Native Synonyms under the following conditions:

- Native Synonyms must be created from a TABLE or VIEW base object.
- The base object (TABLE or VIEW) must exist on the MS SQL Server targeted by the adapter connection string.
- Native Synonyms must be created with the base object described by a name consisting of not more than three components. Depending on the location and ownership of the base object within the targeted server, acceptable formats, are:

  object_name, schema_name.object_name,

  or

  database_name.schema_name.object_name.

The following types of Native Synonyms are not supported:
Those based on stored procedures.

Those based on objects existing on a linked MS SQL server.

Those based on objects described with a 4-part name, such as:

```
server_name.database_name.schema_name.object_name
```

The Dynamic Columns (NOCOLS) and Cardinality (WITHSTATS) parameters are not supported when creating metadata for a Native Synonym.

Note that creating a synonym for a stored procedure is described with reporting against a stored procedure, in *Generating a Synonym for a Stored Procedure* on page 1327.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   The *Select adapter to configure or Select connection to create synonym* pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.
Reference: Synonym Creation Parameters for Microsoft SQL Server

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Important: If you select Stored Procedures as your object type, the input parameters will be a little different from those described here. For details, refer to Creating a Report Against a Stored Procedure on page 1331.

Database selection

To specify a database from which you can select a table or other object, do one of the following:

- Check Use current database to use the database that has been set as the default database.
- Select a database from the Select database drop-down list, which lists all databases in the current DBMS instance.

Before selecting a database, if Use current database is checked, uncheck it.

To specify the intended database, choose from the Select database drop-down menu, which shows all databases on the targeted instance of Microsoft SQL Server. Selecting Default Database will retain the database set during connection configuration. If Default Database was not set during configuration, the database assigned to the active login on the SQL Server will be used as the default.
Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the Base Location field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the Document Name field, enter the file name with or without wildcard characters.

- In the Document Extension field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the Base Location field, enter:

```
/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
```

- The Document Extension is understood to be MBR. You can enter this value explicitly or leave the input box blank.
During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

**With foreign key**

Select the *With foreign key* check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.
Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Microsoft SQL Server Data Type Support on page 1315.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Microsoft SQL Server synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

FILE=DIVISION, SUFFIX=SQLMSS ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON ,$
Generated Access File nf29004.acx

SEGNAME=SEG1_4,TABLENAME=edaqa.nf29004, CONNECTION=connmss, KEYS=1, WRITE=YES,$

Reference: Mapping Microsoft SQL Table Comments Into a Synonym

When you generate a synonym for a Microsoft SQL table, the adapter maps comments as follows:

- MS SQL Server table comments (if present) are mapped to the REMARKS attribute in the Master File synonym.
- MS SQL Server column comments (if present) are mapped to the DESCRIPTION attribute in the Master File synonym.

Both Unicode and non-Unicode comments are supported.

Reference: Access File Keywords

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
</tbody>
</table>
| TABLENAME | Identifies the Microsoft SQL Server table. The table name can be fully qualified as follows:  

TABLENAME=[[database.]owner.]table

| CONNECTION | Indicates a previously declared connection. The syntax is:  

CONNECTION=connection

CONNECTION='' indicates access to the local database server.  
Absence of the CONNECTION attribute indicates access to the default database server. |
| KEYS       | Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first \( n \) fields in the Master File segment. |
| WRITE      | Specifies whether write operations are allowed against the table.          |
Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.

- KEYFLD is the FIELDNAME of the common column from the parent table.
- IXFLD is the FIELDNAME of the common column from the related table.

KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.

**Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEYFLD IXFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the</td>
</tr>
<tr>
<td></td>
<td>relationships established by the multi-table Master File. Together, KEYFLD</td>
</tr>
<tr>
<td></td>
<td>and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td></td>
<td>- KEYFLD is the FIELDNAME of the common column from the parent table.</td>
</tr>
<tr>
<td></td>
<td>- IXFLD is the FIELDNAME of the common column from the related table.</td>
</tr>
<tr>
<td></td>
<td>KEYFLD and IXFLD must have the same data type. It is recommended, but not</td>
</tr>
<tr>
<td></td>
<td>required, that their lengths also be the same.</td>
</tr>
</tbody>
</table>

**Reference:** Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If</td>
</tr>
<tr>
<td></td>
<td>an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <em>Note:</em> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <em>Note:</em> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><em>Note:</em> This option is not available in the Web Console.</td>
</tr>
</tbody>
</table>
Option | Description
--- | ---
Impact Analysis | Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.
Copy | Copies the synonym to the clipboard.
Delete | Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.
Cut | Deletes the synonym and places it on the clipboard.
Properties | Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

</tr>
<tr>
<td>BINARY (n)</td>
<td>n is an integer between 1 and 8000, ( m = 2 \times n ).</td>
<td>Am</td>
<td>Am</td>
</tr>
<tr>
<td>VARBINARY (n)</td>
<td>n is an integer between 1 and 8000, ( m = 2 \times n ).</td>
<td>AmV</td>
<td>AmV</td>
</tr>
<tr>
<td>SQL_VARIANT</td>
<td></td>
<td>A4000V</td>
<td>A4000V</td>
</tr>
</tbody>
</table>

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.
**Reference: Data Type Support for Unicode**

The following table describes how the Unicode server maps Character data types. The server operates in character semantic when configured for Unicode. The LONGCHAR does not affect mapping in this case.

<table>
<thead>
<tr>
<th>Microsoft SQL Server Data Type</th>
<th>Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n) double-byte code page</td>
<td>AnV AnV</td>
<td>(n) is an integer between 1 and 8000. This data type does not support Unicode. However, character columns such as CHAR that had been created with different code pages can be read at the same time only if the server has been configured for Unicode.</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>An An</td>
<td>(n) specifies the number of characters, and is an integer between 1 and 4000. This data type supports Unicode.</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>AnV AnV</td>
<td>(n) is an integer between 1 and 8000. This data type does not support Unicode. However, character columns such as VARCHAR that had been created with different code pages can be read at the same time only if the server has been configured for Unicode.</td>
</tr>
<tr>
<td>NVARCHAR (n)</td>
<td>AnV AnV</td>
<td>(n) specifies the number of characters, and is an integer between 1 and 4000. This data type supports Unicode.</td>
</tr>
</tbody>
</table>
Controlling the Mapping of Large Character Data Types

How to:
Control the Mapping of Large Character Data Types

The SET parameter CONVERSION LONGCHAR controls the mapping of supported Microsoft SQL Server data types listed below. By default, the server maps these data types as alphanumeric (A). The server data type A supports a maximum of 4096 characters for TABLE/MODIFY and 32768 characters for API applications.

Syntax:  
**How to Control the Mapping of Large Character Data Types**

ENGINE SQLMSS SET CONVERSION LONGCHAR {ALPHA | TEXT | BLOB}

where:

**SQLMSS**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ALPHA**
Maps the Microsoft SQL Server data types CHAR, NCHAR, VARCHAR, BINARY, and VARBINARY as alphanumeric (A). ALPHA is the default value.

**TEXT**
Maps the Microsoft SQL Server data types CHAR, NCHAR, VARCHAR, BINARY, and VARBINARY as text (TX). Use this value for WebFOCUS applications.

**BLOB**
For Windows is identical to ALPHA. That is, it maps the Microsoft SQL Server data types CHAR, NCHAR, and VARCHAR as alphanumeric (A).

Controlling the Mapping of Variable-Length Data Types

How to:
Control the Mapping of Variable-Length Data Types

The SET parameter VARCHAR controls the mapping of the Microsoft SQL Server data type VARCHAR. By default, the server maps these data types as variable character (AnV).

The following table lists data type mappings based on the value of VARCHAR:
### Syntax: How to Control the Mapping of Variable-Length Data Types

**ENGINE SQLMSS SET VARCHAR {ON | OFF}

**where:**

**SQLMSS**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Maps the Microsoft SQL Server data type VARCHAR as variable-length alphanumeric (AnV). This is required for Unicode environments. ON is the default value.

**OFF**

Maps the Microsoft SQL Server data type VARCHAR as alphanumeric (A).

### Enabling National Language Support

**How to:**

Enable National Language Support

The SET parameter NCHAR indicates whether the character set is single-byte, double-byte, or triple-byte. The NCHAR setting affects the mapping of NCHAR and NVARCHAR data types.
The following chart lists data type mappings based on the value of NCHAR.

<table>
<thead>
<tr>
<th>Microsoft SQL Server Data Type</th>
<th>Remarks</th>
<th>NCHAR SBCS</th>
<th>NCHAR DBCS</th>
<th>NCHAR TBCS</th>
</tr>
</thead>
</table>
| NCHAR (n)                      | n is an integer between 1 and 4000  
               \m d = 2 * n  
               \m t = 3 * n | An | Ad | At |
| NVARCHAR (n)                   | n is an integer between 1 and 4000  
               \m d = 2 * n  
               \m t = 3 * n | An | Ad | At |

**Syntax:**  
How to Enable National Language Support

The available parameters are:

ENGINE SQLMSS SET NCHAR {SBCS|DBCS|TBCS}

where:

**SQLMSS**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**SBCS**

Indicates a single-byte character set. SBCS is the default value.

**DBCS**

Indicates a double-byte character set.

**TBCS**

Indicates a triple-byte character set.

**Trailing Blanks in SQL Expressions**

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

ENGINE SQLMSS SET TRIM_LITERALS ON
Changing the Precision and Scale of Numeric Columns

How to:
Override the Default Precision and Scale

Example:
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

Syntax:  How to Override the Default Precision and Scale

ENGINE SQLMSS SET CONVERSION RESET
ENGINE SQLMSS SET CONVERSION format RESET
ENGINE SQLMSS SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLMSS SET CONVERSION format [PRECISION MAX]

where:

SQLMSS
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

RESET
Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

format
Is any valid format supported by the data source. Possible values are:

INTEGER which indicates that the command applies only to INTEGER columns.
DECIMAL which indicates that the command applies only to DECIMAL columns.
**REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.

**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```
ENGINE SQLMSS SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```
ENGINE SQLMSS SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```
ENGINE SQLMSS SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```
ENGINE SQLMSS SET CONVERSION RESET
```

**Support of Read-Only Fields**

**Example:** Supporting a Read-Only Field

CREATE SYNONYM creates a field description with FIELDTYPE=R for Microsoft SQL Server columns created as TIMESTAMP or columns with the IDENTITY attribute. These fields are read-only. When executing a MAINTAIN or MODIFY procedure, the adapter suppresses all write operations against columns marked in the Master File with FIELDTYPE=R.

**Example:** Supporting a Read-Only Field

This example creates a table in which the first column has the IDENTITY property and the second column is a timestamp column:

```
CREATE TABLE TAB1
(idproptab int IDENTITY (1,1), timstmp timestamp)
```

CREATE SYNONYM generates the following Master File for this table:

```
FILE=TAB1, SUFFIX=SQLMSS ,$
SEGNAME=TAB1, SEGTYPE=S0 ,$
FIELD=IDPROPTAB, idproptab, I11, I4,  MISSING=OFF, FIELDTYPE=R ,$
FIELD=TIMSTMP, timstmp, A16, A16, MISSING=ON, FIELDTYPE=R ,$
```
Reporting Against a Microsoft SQL Server Stored Procedure

In this section:
Generating a Synonym for a Stored Procedure
Creating a Report Against a Stored Procedure

You can use a reporting tool, such as a SELECT statement or TABLE command, to execute Microsoft SQL Server stored procedures and report against the procedure output parameters and answer set. Among the benefits of this method of executing a stored procedure are:

- The retrieval of output parameters: OUT parameters, and INOUT parameters in OUT mode, as well as the answer set. (Other methods of invocation retrieve the answer set only.)
- The ease with which you can process, format, and display output parameters and the answer set, using TABLE and other reporting tools.

To report against a stored procedure:

1. Generate a synonym for the stored procedure answer set, as described in Generating a Synonym for a Stored Procedure on page 1327.
2. Create a report procedure, as described in Creating a Report Against a Stored Procedure on page 1331.
3. Run the report. This executes the stored procedure and reports against any output parameters (OUT and INOUT in OUT mode), and any answer set fields, specified in the report.

Generating a Synonym for a Stored Procedure

Example:
Synonym for Microsoft SQL Server Stored Procedure CustOrders

Reference:
Synonym Creation Parameters for Stored Procedures

A synonym describes the stored procedure parameters and answer set.
An answer set structure may vary depending on the input parameter values that are provided when the procedure is executed. Therefore, you need to generate a separate synonym for each set of input parameter values that will be provided when the procedure is executed at run time. For example, if users may execute the stored procedure using three different sets of input parameter values, you need to generate three synonyms, one for each set of values. (Unless noted otherwise, input parameters refers to IN parameters and to INOUT parameters in IN mode.)

**There is an exception.** If you know the internal logic of the procedure, and are certain which range of input parameter values will generate each answer set structure returned by the procedure, you can create one synonym for each answer set structure, and for each synonym simply provide a representative set of the input parameter values necessary to return that answer set structure.

A synonym includes the following segments:

- **INPUT**, which describes any IN parameters and INOUT parameters in IN mode.
  - If there are no IN parameters or INOUT parameters in IN mode, the segment describes a single dummy field.

- **OUTPUT**, which describes any OUT parameters and INOUT parameters in OUT mode.
  - If there are no OUT parameters or INOUT parameters in OUT mode, the segment is omitted.

- **ANSWERSETn**, one for each answer set.
  - If there is no answer set, the segment is omitted.

**Example: Synonym for Microsoft SQL Server Stored Procedure CustOrders**

The following synonym describes a Microsoft SQL Server stored procedure with one input parameter, one output parameter, and one answer set containing four variables.
The Master File synonym is:

```
FILENAME=CUSTORDERS, SUFFIX=SQLMSS , $
SEGMENT=INPUT, SEGTYPE=S0, $
   FIELDNAME=@CUSTOMERID, ALIAS=P0001, USAGE=A5, ACTUAL=A5, $
   MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
SEGMENT=OUTPUT, SEGTYPE=S0, PARENT=INPUT, $
   FIELDNAME=@RETURN_VALUE, ALIAS=P0000, USAGE=I11, ACTUAL=I4, $
SEGMENT=ANSWERSET1, SEGTYPE=S0, PARENT=INPUT, $
   FIELDNAME=ORDERID, ALIAS=OrderID, USAGE=I11, ACTUAL=I4, $
   FIELDNAME=ORDERDATE, ALIAS=OrderDate, USAGE=HYYMDs, ACTUAL=HYYMDs, 
   MISSING=ON, $
   FIELDNAME=REQUIREDDATE, ALIAS=RequiredDate, USAGE=HYYMDs, 
   ACTUAL=HYYMDs, MISSING=ON, $
   FIELDNAME=SHIPPEDDATE, ALIAS=ShippedDate, USAGE=HYYMDs, 
   ACTUAL=HYYMDs, MISSING=ON, $
```

The Access File synonym is:

```
SEGNAME=INPUT, CONNECTION=ITarget, STPNAME=Northwind.dbo.CustOrders, $
SEGNAME=OUTPUT, STPRESORDER=0, $
SEGNAME=ANSWERSET1, STPRESORDER=1, $
```

**Reference:** Synonym Creation Parameters for Stored Procedures

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

- Select **Stored Procedures**.

**Database selection**

To specify a database from which you can select a table or other object, do one of the following:

- Check **Use current database** to use the database that has been set as the default database.

- Select a database from the **Select database** drop-down list, which lists all databases in the current DBMS instance.

Before selecting a database, if **Use current database** is checked, uncheck it.
Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Note:** For DB2, this applies to all platforms except IBM i.

Select

Select a procedure. You may only select one procedure at a time since each procedure will require unique input in the Values box on the next synonym creation pane.

Name

The name of the synonym, which defaults to the stored procedure name.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have stored procedures with identical names, assign a prefix or a suffix to distinguish their corresponding synonyms. Note that the resulting synonym name cannot exceed 64 characters.

If all procedures have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Microsoft SQL Server Data Type Support on page 1315.

Values

Select the check box for every parameter displayed for the specified procedure.

Note the following before you enter parameter values: if the procedure you selected has input parameters (IN parameters and/or INOUT parameters in IN mode), you will be prompted to enter values for them. However, the need for an explicit Value entry depends on the logic of the procedure and the data structures it produces. Therefore, while you must check the parameter box, you may not need to enter a value. Follow these guidelines:

- Explicit input values (and separate synonyms) are required when input parameter values cause answer sets with different data structures, which vary depending on the input parameters provided.

- Explicit input values are not required when you know the procedure's internal logic and are certain that it always produces the same data structure. In this situation, only one synonym needs to be created and you can leave the Value input blank for synonym creation purposes.

If a Value is required, enter it without quotes. Any date, date-time, and timestamp parameters must have values entered in an ISO format. Specify the same input parameters that will be provided when the procedure is executed at run time if it is a procedure that requires explicit values.

Creating a Report Against a Stored Procedure

How to:

Report Against a Stored Procedure Using the TABLE Command
Report Against a Stored Procedure Using SELECT

You can report against a stored procedure answer set using the same facilities you use to report against a database table:

- **SQL SELECT statement.** For syntax, see How to Report Against a Stored Procedure Using SELECT on page 1333.

- **TABLE and GRAPH commands.** For syntax, see How to Report Against a Stored Procedure Using the TABLE Command on page 1332.
When joining from or to a stored procedure answer set, you can:

- **Join from** only OUTPUT and ANSWERSET segments in a host file.
- **Join to** only INPUT segments in a cross-referenced file.

### Syntax: How to Report Against a Stored Procedure Using the TABLE Command

To execute a stored procedure using the TABLE command, use the following syntax:

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
.
.
END
```

where:

- **synonym**
  - Is the synonym of the stored procedure you want to execute.

- **parameter**
  - Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.
  - If the stored procedure does not require parameters, specify an asterisk (*). This displays a dummy segment, created when the synonym is generated, to satisfy the structure of the SELECT statement.

- *****
  - Indicates that you want to display all indicated parameters, or that there are no required parameters.

- **IF**
  - Is an IF or WHERE keyword. Use this to pass a value to an IN parameter or an INOUT parameter in IN mode.

- **in-parameter**
  - Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

**Note:** The length of in-parameters cannot exceed 1000 characters if the adapter is configured for Unicode support.

- **value**
  - Is the value you are passing to a parameter.
**Syntax:**  How to Report Against a Stored Procedure Using SELECT

```
SQL
SELECT [parameter [,parameter] ... | *) FROM synonym
[WHERE in-parameter = value]
.
.
.
END
```

where:

**synonym**
Is the synonym of the stored procedure that you want to execute.

**parameter**
Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, enter an asterisk (*) in the syntax. This displays a dummy segment, created during synonym generation, to satisfy the structure of the SELECT statement.

**\*\**
Indicates that you want to display all indicated parameters, or that there are no required parameters.

**WHERE**
Is used to pass a value to an IN parameter or an INOUT parameter in IN mode.
You must specify the value of each parameter on a separate line.

**in-parameter**
Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

**value**
Is the value you are passing to a parameter.
In this section:
Specifying a Timeout Limit
Cancelling Long Requests
Specifying the Cursor Type
Specifying the Login Wait Time
Activating NONBLOCK Mode
Obtaining the Number of Rows Updated or Deleted
Controlling Transactions
Specifying the Transaction Isolation Level

The Adapter for Microsoft SQL Server provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.

Specifying a Timeout Limit

How to:
Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to Microsoft SQL Server.

Syntax: How to Issue the TIMEOUT Command

ENGINE SQLMSS SET TIMEOUT {nn|0}

where:

SQLMSS
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn
Is the number of seconds before a time-out occurs. 30 is the default value.

0
Represents an infinite period to wait for a response.
Cancelling Long Requests

How to:
Cancel Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose Workspace, Configuration/Monitor, Java Services, DEFAULT. Right-click on DEFAULT and select Agents.

2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select Stop.

Specifying the Cursor Type

How to:
Specify the Cursor Type

You can use the SET CURSORS command to specify the type of cursors for retrieval.

Syntax: How to Specify the Cursor Type

The available parameters are:

ENGINE SQLMSS SET CURSORS [CLIENT|SERVER]

where:

CLIENT
Uses Microsoft SQL Server client-side cursors for retrieving data. Client-side cursors normally demonstrate the best performance for data retrieval and benefit the Microsoft SQL Server process. However, except in TRANSACTIONS AUTOCOMMITTED mode, using client-side cursors prevents a server agent from simultaneously reading more than one answer set from the same instance of Microsoft SQL Server.
SERVER

Uses Microsoft SQL Server server-side cursors for retrieving data. Server-side cursors demonstrate lower performance than client cursors. However, setting a high FETCHSIZE factor (100 is the adapter default) improves performance dramatically making them almost as fast as client-side cursors. Client-side cursors are recommended wherever possible to take the load off the Microsoft SQL Server process.

blank

Uses client-side cursors in TRANSACTIONS AUTOCOMMITTED mode and server-side cursors otherwise. This value is the default.

**Specifying the Login Wait Time**

**How to:**
Specify the Login Wait Time

You can use the LOGINTIMEOUT command to specify the number of seconds the adapter will wait for a response from Microsoft SQL Server at connect time.

**Note:** For compatibility with previous releases of the adapter, TIMEOUT is available as a synonym for LOGINTIMEOUT.

**Syntax:**

**How to Specify the Login Wait Time**

ENGINE SQLMSS SET LOGINTIMEOUT|TIMEOUT {nn|0}

where:

**SQLMSS**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**nn**

Is the number of seconds before a timeout occurs. The default value is approximately 15 seconds.

**0**

Represents an infinite period to wait for login response.
Activating NONBLOCK Mode

**How to:**
Activate NONBLOCK Mode

The Adapter for Microsoft SQL Server has the ability to issue calls in NONBLOCK mode. The default behavior is BLOCK mode.

This feature allows the adapter to react to a client request to cancel a query while the adapter is waiting on engine processing. This wait state usually occurs during SQL parsing, before the first row of an answer set is ready for delivery to the adapter or while waiting for access to an object that has been locked by another application.

**Syntax:**

**How to Activate NONBLOCK Mode**

The available parameters are:

\[
\text{ENGINE SQLMSS SET NONBLOCK \{0|n\}}
\]

where:

**SQLMSS**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**n**
Is a positive numeric number. 0 is the default value, which means that the adapter will operate in BLOCK mode. A value of 1 or greater activates the NONBLOCK calling and specifies the time, in seconds, that the adapter will wait between each time it checks to see if the:

- Query has been executed.
- Client application has requested the cancellation of a query.
- Kill Session button on the Web Console is pressed.

**Note:** A value of 1 or 2 should be sufficient for normal operations.
Obtaining the Number of Rows Updated or Deleted

**How to:**
Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

**Syntax:**
**How to Obtain the Number of Rows Updated or Deleted**

The available parameters are:

```sql
ENGINE SQLMSS SET PASSRECS {ON | OFF}
```

where:

- **SQLMSS**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **ON**
  Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

- **OFF**
  Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Controlling Transactions

**How to:**
Control Transactions

You can use the SET TRANSACTIONS command to control how the adapter handles transactions.
**Syntax:**

**How to Control Transactions**

The available parameters are:

```sql
ENGINE SQLMSS SET TRANSACTIONS {LOCAL|DISTRIBUTED|AUTOCOMMITTED}
```

where:

**SQLMSS**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**LOCAL**

Indicates that the adapter implicitly starts a local transaction on each of the connections where any work is performed. At the time of COMMIT or ROLLBACK, or at the end of the server session, the adapter commits or aborts the work on each connection consecutively. LOCAL is the default value.

**DISTRIBUTED**

Indicates that the adapter implicitly invokes Microsoft Distributed Transactions Coordinator (DTC) to create a single distributed transaction within which to perform all work on all the connections. At the time of COMMIT or ROLLBACK, or at the end of the server session, the adapter invokes DTC to execute the two-phase commit or rollback protocol. For this purpose, the DTC service must be started on the machine where the server is running and also on all the machines where involved instances of Microsoft SQL Server reside. This mode is recommended for read-write applications that perform updates on multiple connections simultaneously.

**AUTOCOMMITTED**

Indicates that each individual operation with Microsoft SQL Server is immediately committed (if successful) or rolled back (in case of errors) by the SQL Server. This is recommended for read-only applications for performance considerations. It is not recommended for read-write applications because in this mode it is impossible to roll back a logical unit of work that consists of several operations.

**Specifying the Transaction Isolation Level**

**How to:**

**Specify Transaction Isolation Level From a SET Command**

You can specify the transaction isolation level from the Web Console or using the SET ISOLATION command.
**Syntax:** How to Specify Transaction Isolation Level From a SET Command

You can specify transaction isolation level by issuing the following command

```sql
ENGINE SQLMSS SET ISOLATION {RU|RC|RR|SE|CH|CS}
```

where:

**RU**
Sets the transaction isolation level to Read Uncommitted.

**RC**
Sets the transaction isolation level to Read Committed.

**RR**
Sets the transaction isolation level to Repeatable Read.

**SE**
Sets the transaction isolation level to Serializable Read.

**CH**
Sets the transaction isolation level to Chaos.

**CS**
Sets the transaction isolation level to Cursor Stability, which is a synonym for Read Committed.

**Optimization Settings**

**In this section:**
- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields
- Optimizing Requests if a Virtual Field Contains Null Values
- Optimizing Requests to Pass Virtual Fields Defined as Constants
- Specifying Block Size for Retrieval Processing
- Optimizing Non-Equality WHERE-Based Left Outer Joins

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

**How to:**
Optimize Requests

**Example:**
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

**Reference:**
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

```
SQL SQLMSS SET {OPTIMIZATION|SQLJOIN} setting
```

where:

**SQLMSS**
Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**SQLJOIN**
Is a synonym for OPTIMIZATION.

**setting**
Is the optimization setting. Valid values are as follows:

**ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

**OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example: SQL Requests Passed to the RDBMS With Optimization OFF**

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLMSS SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
    TABLE FILE EMPINFO
    SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
    IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
    FROM 'USER1'.EMPINFO T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.FUNDTRAN T2 WHERE (T2.EID = ?)
    FOR FETCH ONLY;
```

**Example: SQL Requests Passed to the RDBMS With Optimization ON**

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLMSS SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
    TABLE FILE EMPINFO
    SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
    IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.'EMPINFO' T1, 'USER1'.'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID, T1.LN
ORDER BY T2.EID, T1.LN;
```

**Reference:** SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:**
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
**Syntax:** How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLMSS SET OPTIFTHENELSE {ON | OFF}
```

where:

- **SQLMSS** indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.
- **ON** enables IF-THEN-ELSE optimization. This is the default.
- **OFF** disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
SQL SQLMSS SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = ' ') AND (T1.'FN' = ' '))
  AND (T1.'DPT' = 'MIS'));
```
**Example:** Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
SQL SQLMSS SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
    ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX:last_name IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
    WHERE (((T1.'LN' = 'SMITH')));
```}

```sql
TABLE FILE EMPINFO
SUM MAX:last_name IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
    WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```}

**Example:** Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```sql
SQL SQLMSS SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
Reference: SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  
  \[ X = X + 1; \]

- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

  **Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.

- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.

- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

  **Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.

- STATIC SQL.

- IF/WHERE DDNAME.

- Partial date selection.
Optimizing Requests if a Virtual Field Contains Null Values

**How to:**
Set Enhanced Aggregation Control

**Example:**
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**
SQL Limitations on Optimization of DEFINE Expressions

The SET OPTNOAGGR command provides finely-tuned control of adapter behavior for optimization. Users who for any reason wish to prevent passing aggregation to the RDBMS can use this command. An example of such a reason might be where NULL values occur in aggregated data with calculations. The SET OPTNOAGGR command causes the adapter to generate SQL without passing aggregation to the DBMS. Aggregation is instead performed internally by the server while JOIN and SORT operations are handled by the RDBMS.

If any DEFINE field contains calculations with NULL fields then such operations cannot be translated to SQL and pass to DBMS because always return NULL. It has to be processed by FOCUS.

This can be achieved by SET OPTIMIZATION OFF.

However, in some cases it is preferable to use the off-load JOIN and SORT operation to DBMS for better performance while leaving AGGREGATION to FOCUS.

**Syntax:**

**How to Set Enhanced Aggregation Control**

```sql
SQL SQLMSS SET OPT {AGGR | NOAGGR}
```

where:

- **AGGR**
  
  Directs the adapter to off-load aggregated DEFINE fields to the DBMS. This is the default setting.

- **NOAGGR**
  
  Directs the adapter to generate SQL without passing aggregation to the DBMS. Aggregation is, instead, performed internally by the server, while JOIN and SORT operations are handled by the RDBMS. This setting can also be used to provide backwards compatibility for applications that were written based on the functionality of the previous release, when less SQL was off-loaded to the RDBMS. For example, when a calculation on aggregated fields may have contained NULL data that was not processed by the RDBMS NVL( ) function.
**Example:** Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```sql
SQL SQLMSS SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END
```

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1."FN" FROM USER1."EMPINFO" T1 WHERE (1 = 0) FOR FETCH ONLY;
```

**Reference:** SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  ```sql
  X=X+1;
  ```
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).
Note: FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.

Optimizing Requests to Pass Virtual Fields Defined as Constants

Example:

Passing Numeric Constants
Passing a CHAR Constant
Passing CHAR and INTEGER Constants

A virtual field defined as a constant is passed directly to an SQL database engine (RDBMS) for optimized processing that takes advantage of RDBMS join, sort, and aggregation capabilities, thus reducing the volume of RDBMS-to-server communication and improving response time. (In prior releases, constants were not passed to the database engine, causing optimization to be turned off.)

Constants in the following formats are passed to the RDBMS: NUMERIC, CHAR, VARCHAR, CHAR/INTEGER combination, and DATE. (Note that a few formats are not passed to the RDBMS; these are CHAR and VARCHAR combination, TIME, and DATETIME.)

When valid constants are passed to an RDBMS engine, a report is calculated based on the defined value(s) and only the calculated subset of records is returned. The extent of data manipulaton at the adapter level is limited, thereby improving performance.

Example: Passing Numeric Constants

DEFINE FILE SMIX87
INTEGERCONST/I4 = 5
REALCONST/D20.2 = -97995.38
NUMERICCONST/P13.4 = -92999.3647

TABLE FILE SMIX87
SUM INTEGERCONST REALCONST NUMERICCONST MAX.QUOT.FA01INTEGER
BY QUOT.FA02INTEGER
END
The following SQL is generated:

```
SELECT T2."FA02INTEGER", SUM(5), SUM(-97995.38),
    SUM(-92999.3647), MAX(T2."FA01INTEGER") FROM TMIX83A T2 GROUP
    BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Example: Passing a CHAR Constant**

```
DEFINE FILE SMIX87
    CHARCONST/A10 = '2N'

TABLE FILE SMIX87
    SUM CHARCONST MIN.FA02CHAR_15
    BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), MIN(T3."FA02CHAR_15") FROM
    TMIX83A T2,TMIX86A T3 WHERE (T3."FA01INTEGER" =
    T2."FA01INTEGER") GROUP BY T2."FA02INTEGER" ORDER BY
    T2."FA02INTEGER";
```

**Example: Passing CHAR and INTEGER Constants**

```
DEFINE FILE SMIX87
    CHARCONST/A10 = '2N'
    INTEGERCONST/I4 = 5

TABLE FILE SMIX87
    SUM CHARCONST INTEGERCONST
    BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), SUM(5) FROM TMIX83A T2
    GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```
Specifying Block Size for Retrieval Processing

How to:
Specify Block Size for Array Retrieval
Specify Block Size for Insert Processing
Suppress the Bulk Insert API

Reference:
Bulk Insert API Behavior

The Adapter for Microsoft SQL Server supports array retrieval from result sets produced by executing SELECT queries or stored procedures. This technique substantially reduces network traffic and CPU utilization.

Using high values increases the efficiency of requests involving many rows, at the cost of higher virtual storage requirements. A value higher than 100 is not recommended because the increased efficiency it would provide is generally negligible.

Tip: You can change this setting manually or from the Web Console by clicking Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the right-click menu. The Change Settings pane opens.

Syntax: How to Specify Block Size for Array Retrieval

The block size for a SELECT request applies to TABLE FILE requests, MODIFY requests, MATCH requests, and DIRECT SQL SELECT statements.

ENGINE SQLMSS SET FETCHSIZE n

where:

SQLMSS
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n
Is the number of rows to be retrieved at once using array retrieval techniques. Accepted values are 1 to 5000. The default varies by adapter. If the result set contains a column that has to be processed as a CLOB or a BLOB, the FETCHSIZE value used for that result set is 1.
**Syntax:** How to Specify Block Size for Insert Processing

In combination with LOADONLY, the block size for an INSERT applies to MODIFY INCLUDE requests. INSERTSIZE is also supported for parameterized DIRECT SQL INSERT statements.

```sql
ENGINE SQLMSS SET INSERTSIZE \n```

where:

- **SQLMSS**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- \n  Is the number of rows to be inserted using array insert techniques. Accepted values are 1 to 5000. 1 is the default value. If the result set contains a column that has to be processed as a BLOB, the INSERTSIZE value used for that result set is 1.

**Syntax:** How to Suppress the Bulk Insert API

```sql
ENGINE SQLMSS SET FASTLOAD [ON | OFF]
```

where:

- **SQLMSS**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **ON**
  Uses the Bulk Insert API. ON is the default.

- **OFF**
  Suppresses the use of the Bulk Insert API.

**Reference:** Bulk Insert API Behavior

You can use DataMigrator with the Bulk Insert API for Microsoft SQL Server.

For the Adapter for Microsoft SQL Server, the Bulk API is used automatically in LOADONLY mode. Measurements show that intermediate flushes do not affect performance; therefore, the behavior does not depend on the INSERTSIZE.

Errors that occur during the load (such as duplication) can cause the batch of rows to be rejected as a whole.
Optimizing Non-Equality WHERE-Based Left Outer Joins

**How to:**
Specify a Conditional Left Outer JOIN

**Example:**
Optimizing a Non-Equality Left Outer Join

**Reference:**
Conditions for WHERE-Based Outer Join Optimization

A left outer join selects all records from the host table and matches them with records from the cross-referenced table. When no matching records exist, the host record is still retained, and default values (blank or zero) are assigned to the cross-referenced fields. The adapter can optimize any WHERE-based left outer join command in which the conditional expression is supported by the RDBMS.

Syntax: **How to Specify a Conditional Left Outer JOIN**

```
JOIN LEFT_OUTER FILE hostfile AT hfld1 [TAG tag1]
    [WITH hfld2]
    TO {UNIQUE|MULTIPLE}
    FILE crfile AT crfld [TAG tag2] [AS joinname]
    [WHERE expression1;
    [WHERE expression2;
    ...]
END
```

**where:**

**LEFT_OUTER**

Specifies a left outer join. If you do not specify the type of join in the JOIN command, the ALL parameter setting determines the type of join to perform.

**hostfile**

Is the host Master File.

**AT**

Links the correct parent segment or host to the correct child or cross-referenced segment. The field values used as the AT parameter are not used to cause the link. They are used as segment references.
Is the field name in the host Master File whose segment will be joined to the cross-referenced data source. The field name must be at the lowest level segment in its data source that is referenced.

Is the optional tag name that is used as a unique qualifier for fields and aliases in the host data source.

WITH hfld2

Is a data source field with which to associate a DEFINE-based conditional JOIN. For a DEFINE-based conditional join, the KEEPDEFINES setting must be ON, and you must create the virtual fields before issuing the JOIN command.

MULTIPLE

Specifies a one-to-many relationship between from_file and to_file. Note that ALL is a synonym for MULTIPLE.

UNIQUE

Specifies a one-to-one relationship between hostfile and crfile. Note that ONE is a synonym for UNIQUE.

Note: Unique returns only one instance and, if there is no matching instance in the cross-referenced file, it supplies default values (blank for alphanumeric fields and zero for numeric fields).

The unique join is a WebFOCUS concept. The RDBMS makes no distinction between unique and non-unique situations. It always retrieves all matching rows from the cross-referenced file.

If the RDBMS processes a join that the request specifies as unique, and if there are, in fact, multiple corresponding rows in the cross-referenced file, the RDBMS returns all matching rows. If, instead, optimization is disabled so that WebFOCUS processes the join, a different report results because WebFOCUS, respecting the unique join concept, returns only one cross-referenced row for each host row.

Is the cross-referenced Master File.

crfld

Is the join field name in the cross-referenced Master File. It can be any field in the segment.
tag2
Is the optional tag name that is used as a unique qualifier for fields and aliases in the cross-referenced data source.

joinname
Is the name associated with the joined structure.

eexpression1, expression2
Are any expressions that are acceptable in a DEFINE FILE command. All fields used in the expressions must lie on a single path.

Reference: Conditions for WHERE-Based Outer Join Optimization

- In order for a WHERE-based left outer join to be optimized, the expressions must be optimizable for the RDBMS involved and at least one of the following conditions must be true:
  - The JOIN WHERE command contains at least one $field1$ EQ $field2$ predicate in which $field1$ is in $table1$ and $field2$ is in $table2$.
    or
  - The right table has a key or a unique index that does not contain NULL data.
    or
  - The right table contains at least one "NOT NULL" column that does not have a long data type (such as TEXT or IMAGE).
- The adapter SQLJOIN OUTER setting must be ON (the default).
**Example:** Optimizing a Non-Equality Left Outer Join

The following request creates a left outer conditional join between two MSSQL data sources and reports against the joined data sources. The STMTRACE is turned on in order to view the SQL generated for this request:

```
SET TRACEUSER = ON
SET TRACEOFF = ALL
SET TRACEON = STMTRACE//CLIENT
JOIN LEFT_OUTER FILE employee AT EMPLOYEEID
TO ALL FILE employeepayhistory AT EMPLOYEEID
    WHERE RATECHANGEDATE GT HIREDATE;
END
```

```
TABLE FILE employee
PRINT RATE
BY EMPLOYEEID
END
```

The WebFOCUS request is translated to a single MSSQL SELECT statement that incorporates the left outer join, and the non-equality condition is passed to the RDBMS in the ON clause:

```
SELECT T1."EmployeeID", T1."HireDate", T2."EmployeeID", T2."RateChangeDate", T2."Rate" FROM
AdventureWorks.HumanResources.Employee T1
    LEFT OUTER JOIN
AdventureWorks.HumanResources.EmployeePayHistory T2
    ON
    (T2."RateChangeDate" > T1."HireDate")
) ORDER BY T1."EmployeeID";
```

**Calling a Microsoft SQL Server Stored Procedure Using SQL Passthru**

**How to:**
Invoke a Stored Procedure

**Example:**
Invoking a Stored Procedure
Sample Stored Procedure

**Reference:**
Capturing Application Errors in Stored Procedures

Microsoft SQL Server stored procedures are supported using SQL Passthru. These procedures need to be developed within Microsoft SQL Server using the CREATE PROCEDURE command. The adapter supports stored procedures with input, output, and in-out parameters.
The output parameter values that are returned by stored procedures are available as result sets. These values form a single-row result set that is transferred to the client after all other result sets are returned by the invoked stored procedure. The names of the output parameters (if available) become the column titles of that result set.

Note that only the output parameters (and the returned value) referenced in the invocation string are returned to the client. As a result, users have full control over which output parameters have their values displayed.

The server supports invocation of stored procedures written according to the rules of the underlying DBMS. Note that the examples shown in this section are SQL-based. See the DBMS documentation for rules, languages, and additional programming examples.

**Syntax: How to Invoke a Stored Procedure**

```sql
SQL SQLMSS EX procname [parameter_specification1]
[,parameter_specification2]...
END
```

where:

- **SQLMSS**
  - Is the ENGINE suffix for Microsoft SQL Server.

- **procname**
  - Is the name of the stored procedure. It is the fully or partially qualified name of the stored procedure in the native RDBMS syntax.

  You can employ either SQL or SYS naming conventions to control the separator character used for interpreting multipart names, as described in Setting Naming Conventions.

- **parameter_specification**
  - IN, OUT, and INOUT parameters are supported. Use the variation required by the stored procedure:
    - **IN**
      - Is a literal (for example, 125, 3.14, 'abcde'). You can use reserved words as input. Unlike character literals, reserved words are not enclosed in quotation marks (for example, NULL). Input is required.
    - **OUT**
      - Is represented as a question mark (?). You can control whether output is passed to an application by including or omitting this parameter. If omitted, this entry will be an empty string (containing 0 characters).
**INOUT**

Consists of a question mark (?) for output and a literal for input, separated by a slash: /. (For example: ?/125, ?/3.14, ?/’abcde’.) The out value can be an empty string (containing 0 characters).

**Example: Invoking a Stored Procedure**

In this example, a user invokes a stored procedure, edaqa.test_proc01, supplies input values for parameters 1, 3, 5 and 7, and requests the returned value of the stored procedure, as well as output values for parameters 2 and 3.

Note that parameters 4 and 6 are omitted; the stored procedure will use their default values, as specified at the time of its creation.

```sql
SQL SQLMSS EX edaqa.test_proc01 125,?,?/3.14,,'abc',,'xyz'
END
```
Example: Sample Stored Procedure

This stored procedure uses out and inout parameters:

```
CREATE PROCEDURE EDAQA.PROCP3 (
   OUT chSQLSTATE_OUT   CHAR(5),
   OUT intSQLCODE_OUT   INT,
   INOUT l_name char(20),
   INOUT f_name char(20))
RESULT SETS 1
LANGUAGE SQL
```

```sql
-- SQL Stored Procedure
-- -----------------------------------------------
P1: BEGIN
   -- Declare variable
   DECLARE SQLSTATE CHAR(5) DEFAULT '00000';
   DECLARE SQLCODE INT DEFAULT 0;
   -- Declare cursor
   DECLARE cursor1 CURSOR WITH RETURN FOR
   SELECT
       EDAQA.NF29005.SSN5 AS SSN5,
       EDAQA.NF29005.LAST_NAME5 AS LAST_NAME5,
       EDAQA.NF29005.FIRST_NAME5 AS FIRST_NAME5,
       EDAQA.NF29005.BIRTHDATE5 AS BIRTHDATE5,
       EDAQA.NF29005.SEX5 AS SEX5
FROM
   EDAQA.NF29005
WHERE
   ( EDAQA.NF29005.LAST_NAME5 =  l_name )
   AND
   ( EDAQA.NF29005.FIRST_NAME5 = f_name )
;
   -- Cursor left open for client application
   OPEN cursor1;
   SET chSQLSTATE_OUT = SQLSTATE;
   SET intSQLCODE_OUT = SQLCODE;
   SET l_name = 'this is first name';
   SET f_name = 'this is last name';
END P1   @
```

Reference: Capturing Application Errors in Stored Procedures

You can capture application errors using the RAISERROR method. Any application error that is issued by the stored procedure is available in the server variable &MSSMSGTXT.
Microsoft SQL Server Compatibility With ODBC

In this section:
- Microsoft SQL Server Connection Attributes With ODBC
- Microsoft SQL Server Cursors With ODBC
- Mapping of UNIQUEIDENTIFIER and BIT Data Types

Release 5.2 and higher of the Adapter for Microsoft SQL Server is based on OLE DB, the Microsoft-recommended API for developing high-performance components. The adapter uses the OLE DB Provider for SQL Server (SQLOLEDB), a native, high-performance provider that directly accesses the SQL Server TDS protocol.

Releases of the adapter prior to 5.2 were based on the ODBC API. The current release of the adapter supports all the functionality of the earlier, ODBC-based versions. In addition, it introduces the following enhancements:

- Support for distributed transactions.
- Array Retrieval.
- Command execution timeout.
- Fast load. This feature, enabled automatically, improves the performance of load-only DataMigrator applications and MODIFY procedures.
- XA transaction support. For details, see XA Support on page 2757.

Differences between adapter functionality under OLE DB and ODBC exist in the following areas:

- Connection attributes.
- Cursors.
- Mapping of UNIQUEIDENTIFIER and BIT data types.

If you are using ODBC, be sure to review these topics.

Microsoft SQL Server Connection Attributes With ODBC

An ODBC data source declaration contains the following information: the instance of Microsoft SQL Server, the default database, the network libraries, and so on. In earlier, ODBC-based releases of the adapter, the SET CONNECTION_ATTRIBUTES command required only the name of an ODBC data source (User or System DNS) and authentication parameters.
Unlike ODBC data sources, OLE DB data sources directly reference instances of Microsoft SQL Server. To connect to an OLE DB data source, the adapter has to specify all the pertinent parameters at connection time. For this reason, the syntax of the How to Declare Connection Attributes Manually on UNIX and z/OS on page 1302 command has been expanded to account for these parameters and also to provide the ability to declare more than one connection to the same instance of Microsoft SQL Server.

**Microsoft SQL Server Cursors With ODBC**

In earlier, ODBC-based releases of the adapter, the SET parameter CONCUR is used to control the ODBC cursor type. The CONCUR parameter has two settings: RONLY results in client-side cursors, and ROWVER forces cursors to be server-side. Release 5.2 of the adapter takes advantage of OLE DB’s ability to directly control the cursor type using a CURSOR parameter. The SET parameter CURSOR has two settings: CLIENT and SERVER. By default, the adapter assigns cursor properties that provide maximum performance for the given environment.

**Mapping of UNIQUEIDENTIFIER and BIT Data Types**

OLE DB maps the following data types differently than ODBC:

- **UNIQUEIDENTIFIER** is mapped to 38 characters. ODBC maps this data type to 36 characters. This difference results from the fact that OLE DB encloses the value in braces ({}).
- **BIT** is mapped to -1 for TRUE and 0 for FALSE. ODBC maps TRUE to 1.
Using the Adapter for Millennium

The Adapter for Millennium allows applications to access Millennium data sources. The adapter converts application requests into native Millennium statements and returns optimized answer sets to the requesting application.

Topics:
- Preparing the Server Environment for Millennium
- Configuring the Adapter for Millennium
- Preparing the Millennium Environment
- Managing Millennium Metadata
- Standard Master File Attributes for a Millennium Data Source
Preparing the Server Environment for Millennium

How to: Prepare the Server Environment for Millennium

The Adapter for Millennium supports compressed Millennium VSAM files. The Millennium decompression routines have been added through the existing Zcomp1 exit point. To enable support for compressed files, include the following set command is in your server profile, EDASPROF.prf:

```
ENGINE CPMILL SET ZCOMP FOCMILZ
```

The adapter requires two control files to be built and allocated to DDNAME CPMILL and CPMILLI via JCL or DYNAM allocation. The Millennium control file is used as input to these files and is dynamically allocated to the server only for the creation of CPMILL and CPMILLI.

Procedure: How to Prepare the Server Environment for Millennium

Allocate two MVS PDSs, CPMILL and CPMILLI, with no DCB information. DCB information is determined by the server at run time. The space requirements are:

- First extent cylinders: 5
- Secondary cylinders: 2

Sample JCL for CPMILL allocation follows:

```
//ALOCLIB EXEC PGM=IEFBR14
//APPL  DD DSN=HIGHLQ.CPMILL,DISP=(NEW,CATLG),
//      VOL=SER=USERMC,UNIT=3390,SPACE=(CYL,(5,2))
```

Sample JCL for CPMILLI allocation follows:

```
//ALOCLIB EXEC PGM=IEFBR14
//APPL  DD DSN=HIGHLQ.CPMILLI,DISP=(NEW,CATLG),
//      VOL=SER=USERMC,UNIT=3390,SPACE=(CYL,(5,2))
```

Configuring the Adapter for Millennium

How to: Configure the Adapter

You can configure the adapter from the Web Console or the Data Management Console. You must then edit and execute several files to complete the configuration.
Procedure: How to Configure the Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   or
   From the Data Management Console, expand the Adapters folder.
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Note: The Millennium adapter is under the DBMS group folder. No input parameters are required.

Procedure: How to Edit Configuration Files for the Adapter for Millennium

After configuring the adapter from the Web Console, perform the following additional steps:

1. Edit the server profile, EDASPROF, to:
   - Allocate CPMILL and CPMILLI to the server.
Add your GEAC VSAM files, as in the following sample.

```plaintext
ENGINE CPMILL SET ZCOMP FOCMILZ
GEAC Allocations

DYNAM ALLOC FILE CPMILL MOD -
  DATASET HIGHLQ.CPMILL
DYNAM ALLOC FILE CPMILLI MOD -
  DATASET HIGHLQ.CPMILLI
DYNAM ALLOC FILE HRMH0B SHR REU -
  DATASET MKTPJC.GEAC.HR.H33EM1
DYNAM ALLOC FILE H33EM2 SHR REU -
  DATASET MKTPJC.GEAC.HR.H33EM2
DYNAM ALLOC FILE H33EM3 SHR REU -
  DATASET MKTPJC.GEAC.HR.H33EM3
DYNAM ALLOC FILE HRMH7O SHR REU -
  DATASET MKTPJC.GEAC.HR.H33PER
DYNAM ALLOC FILE HRMH7S SHR REU -
  DATASET MKTPJC.GEAC.HR.H33PER
DYNAM ALLOC FILE H33QEH1 SHR REU -
  DATASET MKTPJC.GEAC.HR.H33QEH1
DYNAM ALLOC FILE H33QEH2 SHR REU -
  DATASET MKTPJC.GEAC.HR.H33QEH2
DYNAM ALLOC FILE H33QEH3 SHR REU -
  DATASET MKTPJC.GEAC.HR.H33QEH3
DYNAM ALLOC FILE H33TAX SHR REU -
  DATASET MKTPJC.GEAC.HR.H33TAX
DYNAM ALLOC FILE H33UTL SHR REU -
```

2. Start the server.

3. Using RDAAPP on MVS or the Test Tool on NT, execute the CPMILLI RPC, located in the IBIFEX DDNAME allocation of the server. This procedure uses the Millennium control file as input to populate the CPMILLI control file.

To execute the RPC, you need the dataset name of the Millennium control file (for example, M3000):

```
CPMILLI DSN=GEAC.MILL.M3000
```

After execution, CPMILLI will contain the following records:

```
CDBAMDM3LL
CDBAIM3LL
CDBAMNM3LL
CDBH0BM3LL
CDBH7OM3LL
CDBH7SM3LL
```
4. Edit CPMILLI to associate the Millennium DB_DBIDs, DB_DBSUBIDs, and DB_TRANIDs with the names of the corresponding Master Files, which are delivered with the Millennium product.

<table>
<thead>
<tr>
<th>CPMILLI Record</th>
<th>Master File Name</th>
<th>Edited Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDBAMDM3LL</td>
<td>APMAMD</td>
<td>CDBAMDM3LLAPMAMD</td>
</tr>
<tr>
<td>CDBAMIM3LL</td>
<td>APMAMI</td>
<td>CDBAMIM3LLAPMAMI</td>
</tr>
<tr>
<td>CDBAMNM3LL</td>
<td>APMAMN</td>
<td>CDBAMNM3LLAPMAMN</td>
</tr>
<tr>
<td>CDBH0BM3LL</td>
<td>HRMH0B</td>
<td>CDBH0BM3LLHRMH0B</td>
</tr>
<tr>
<td>CDBH7OM3LL</td>
<td>HRMH0B</td>
<td>CDBH7OM3LLHRMH70</td>
</tr>
<tr>
<td>CDBH7SM3LL</td>
<td>HRMH0B</td>
<td>CDBH7SM3LLHRMH7S</td>
</tr>
</tbody>
</table>

5. Using RDAAP on MVS or the Test Tool on NT, execute the CPMILL RPC, located in the IBIFEX DDNAME allocation of the server. This procedure associates the Millennium control file information with the adapter routines.

CPMILL takes two input parameters: &dsn for the CPMILLI dataset, and &dsn1 for the Millennium control file:

```
CPMILL DSN=HIGHLQ.CPMILLI,DSN1=GEAC.MILL.M30000
```

6. Edit the server profile, EDASPROF, to change the file allocation for CPMILL and CPMILLI from MOD to SHR REU, as shown below:

```bash
_**********************************************************************
 ENGINE CPMILL SET ZCOMP FOCMILZ
*************************************************************************
 GEAC Allocations********
 DYNAM ALLOC FILE CPMILL SHR REU -
     DATASET HIGHLQ.CPMILL
 DYNAM ALLOC FILE CPMILLI SHR REU -
     DATASET HIGHLQ.CPMILLI
```
Preparing the Millennium Environment

Prior to using the server and configuring the Adapter for Millennium using the Web Console, you need to edit the server IRUNJCL procedure.

**Procedure: How to Edit the Server IRUNJCL**

**Procedure overview:**

1. Concatenate the Millennium API modules for the adapter to DDNAME STEPLIB.
2. Allocate the DDNAMEs M30000 and M30002 to your Millennium Control File data sets, if you are running Millennium Release 3.
3. Determine the DDNAMEs for the Millennium databases based on your Millennium installation options. (See your Millennium documentation or contact your Millennium administrator for this information.)
4. Allocate DDNAME FOCPRV to the data set that contains Access Files. You can omit the allocation for DDNAME FOCPRV if all database IDs are assigned using the Master File member name (for more information, see *Managing Millennium Metadata* on page 1369), or access the default lead transaction ID.

Your system support staff can supply proper data set names for your site. The Millennium API modules must be MVS-loadable.

The server must allocate the specific files of the adapter in the IRUNJCL, as well as in a global profile (EDASPROF.CFG).

**Edit the IRUNJCL and EDASPROF.CFG as follows:**

**IRUNJCL.** Millennium load library and Control files and databases:

```plaintext
//M30000 DD DISP=SHR,DSN=millen.ctrlfile.M30000
//M30002 DD DISP=SHR,DSN=millen.ctrlfile.M30002
//database DD DISP=SHR,DSN=millen.database
```

The IRUNJCL must have the following data sets allocated to the following DDNAMEs.

**EDASPROF.CFG.** Millennium Access File data set allocation

```plaintext
//* Millennium ALLOCATIONS
DYNAM ALLOC F FOCPRV DA qualif.FOCPRV.DATA SHR REUSE
```
where:

\textit{milen}\linebreak Is the high-level qualifier for your Millennium production data sets.

\textit{ctrlfile}\linebreak Is the Millennium control file.

\textit{database}\linebreak Is the DDNAME required by Millennium for a Millennium database. If you access more than one Millennium database, you must allocate more than one DDNAME, each determined by the options chosen when your site installed Millennium.

\textit{qualif}\linebreak Is the high-level qualifier for your server production data sets.

\textbf{Adapter Tracing}

To activate the Adapter for Millennium Tracing Facility, you must allocate DDNAME GPTRACE in the server JCL:

//GPTRACE DD SYSOUT=*\linebreak

\textbf{Note:} Use the adapter Tracing Facility carefully. The DDNAME is allocated to the server JCL; therefore, it is applied globally. This causes the adapter activity to be traced for all server tasks. This facility should be used under tightly controlled testing circumstances.

\textbf{Managing Millennium Metadata}

\textbf{In this section:}

Creating Synonyms

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Millennium data types.
Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Creating a Synonym for a Millennium Data Source
Sample COBOL FD

**Reference:**
Synonym Creation Parameters for Millennium
Managing Synonyms
Customization Options for COBOL File Descriptions

Synonyms define unique names (or aliases) for each Millennium file or view that is accessible from the server. Synonyms are useful because they hide the underlying data source’s location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File that represents the server’s metadata.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click **Applications**.
   
   The Applications page opens.

2. Click the **New** button and select **Synonym** from the drop-down menu.
   
   The **Select adapter to configure or Select connection to create synonym** pane opens.

3. Click a connection for the configured adapter.
   
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click **Create Synonym**.
The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the *Validate* check box, the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:** **Synonym Creation Parameters for Millennium**

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

**COBOL FD Selection Options**

**File System**

Select one of the following from the drop-down list:

- *Fully qualified PDS name* to enter a fully qualified MVS Library in the entry box.

- *Absolute HFS directory pathname* to enter the HFS location that contains the COBOL FD.

**PDS name or Directory name**

Depending on your selection for File System, enter the fully qualified PDS name or absolute directory path that contains the COBOL FD.

**Member Name or File Name**

Depending on your selection for File System, enter the member name or file that contains the COBOL FD.

You can enter a string for filtering these names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter ABC% to select names which begin with the letters ABC; %ABC to select names which end with the letters ABC; %ABC% to select names which contain the letters ABC at the beginning, middle, or end.
**File Extension**

If you selected *Absolute HFS directory pathname* as the file system, enter the extension of the file that contains the COBOL FD.

**Select Files and Synonym Names**

For each file that you want to map using a COBOL FD, check the box next to the appropriate file name. Select the check box in the table heading to select all files. You can edit the default synonym names. Enter a cluster name to associate it with a particular metadata description. The cluster name is embedded in the Master File. If you do not enter the cluster name during the synonym creation process, you will have to add it dynamically at run time.

**Additional Options**

**Validate**

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2821 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; '\'; '/'; ','; '$'. No checking is performed for names.

**Make unique**

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

**Customize**

Optionally, select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2775.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.
If all tables and views have unique names, leave the prefix and suffix fields blank.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Example:** Creating a Synonym for a Millennium Data Source

Use the following steps to create a synonym for the DBVSAM01 data source:

1. From the Data Adapters page, click Millennium and select *Create Synonym* from the pop-up menu. (You can also start from the Metadata page by clicking a Millennium connection.)

2. Enter the following information about the COBOL FD for the file system you use:
   - If you select *Fully qualified PDS name*, enter the name of the PDS that contains the COBOL FD and the member name of the COBOL FD.
   - If you select *Absolute HFS directory pathname* enter the path to the COBOL FD and its file name and extension.

3. Select the COBOL FD to use (in this example DBVSAM01). You can accept the default synonym name, which is the same as the COBOL FD file name, or edit the Default Synonym Name column.

4. Enter the cluster name in the Dataset Location column. For example:
   
   `user1.dbvsam01.cluster`

5. Click *Create Synonym*.

   You should get a message indicating that the synonym was created successfully.
6. To view the Master File created, go to the Metadata page, open the application under which you created the synonym, click the synonym name, and select *Edit as Text* from the context menu. This example resulted in the following Master File:

```plaintext
FILENAME=DBVSAM01, SUFFIX=CPMILL, $
DATASET=user1.dbvsam01.cluster, $
  SEGMENT=SEG1, SEGTYPE=S0, $
  $ GROUP=COUNTRY, ALIAS=E1, USAGE=A24, ACTUAL=A24, $
  FIELDNAME=COUNTRY_CODE, ALIAS=E2, USAGE=A8, ACTUAL=A8, $
  FIELDNAME=COUNTRY_NAME, ALIAS=E3, USAGE=A16, ACTUAL=A16, $
```

**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the <em>Open</em> option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>
**Customization Options for COBOL File Descriptions**

You can customize how a COBOL FD is translated by selecting *Customize options* in the Synonym creation pane. The following options are added to the right pane:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>On Error</td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- <em>Continue</em> to continue generating the Master File when an error occurs. Continue is the default value.</td>
</tr>
<tr>
<td></td>
<td>- <em>Abort</em> to stop generating the Master File when an error occurs.</td>
</tr>
<tr>
<td></td>
<td>- <em>Comment</em> to produce a commented Master File when an error occurs.</td>
</tr>
<tr>
<td>Hyphens as</td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- <em>No</em> to remove all hyphens in the COBOL name from the Master File field names.</td>
</tr>
<tr>
<td></td>
<td>- <em>Yes</em> to replace all hyphens in the COBOL name with the underscore character. Yes is the default value.</td>
</tr>
<tr>
<td>Redefines</td>
<td>You may treat COBOL REDEFINE fields in one of three ways. Choose:</td>
</tr>
<tr>
<td></td>
<td>- <em>Segments</em> to describe REDEFINE fields as segments in the Master File. Segments is the default value.</td>
</tr>
<tr>
<td></td>
<td>- <em>Comments</em> to describe REDEFINE fields as comments in the Master File.</td>
</tr>
<tr>
<td></td>
<td>- <em>None</em> to exclude REDEFINE fields altogether.</td>
</tr>
<tr>
<td>Occurs as</td>
<td>Choose <em>Segments</em> to describe OCCURS structures as segments. Otherwise, choose <em>Field</em>. Segments is the default value.</td>
</tr>
<tr>
<td>Alignment</td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- <em>Yes</em> to insert slack bytes into a record to ensure alignment of numeric fields.</td>
</tr>
<tr>
<td></td>
<td>- <em>No</em> to generate Master Files without alignment of slack bytes. No is the default value.</td>
</tr>
<tr>
<td><strong>Parameter</strong></td>
<td><strong>Definition</strong></td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Number of Hyphens to skip</td>
<td>FD Translator removes characters from the left, up to and including the Nth hyphen (depending on the value of N chosen in the menu).</td>
</tr>
<tr>
<td></td>
<td>- 0 retains the entire COBOL name. 0 is the default value.</td>
</tr>
<tr>
<td></td>
<td>- All removes all prefixes.</td>
</tr>
<tr>
<td>Order fields</td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- Yes to generate Order fields in a Master File.</td>
</tr>
<tr>
<td></td>
<td>- No to generate a Master File without Order fields. No is the default value.</td>
</tr>
<tr>
<td>Level 88 as</td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- Comment to include COBOL Level 88 fields as comments in the Master Files.</td>
</tr>
<tr>
<td></td>
<td>- Skip to exclude level 88 fields. Skip is the default value.</td>
</tr>
<tr>
<td>Zoned Numeric Fields</td>
<td>Sets how zoned numeric values will be stored.</td>
</tr>
</tbody>
</table>

**Numeric Field Edit Options**

| **Zeroes**                    | Choose:                                                                                                                                        |
|                               |   - Suppress to suppress printing of the digit zero for a field whose value is zero.                                                         |
|                               |   - Display to display leading zeroes, for example, 00124.                                                                                   |
|                               |   - None for no formatting.                                                                                                                   |

<p>| <strong>Negative value</strong>            | Choose:                                                                                                                                        |
|                               |   - Bracket to bracket negative values, for example, (1234).                                                                                |
|                               |   - Credit to credit negative values, for example, 1234 CR.                                                                                 |
|                               |   - None for no formatting.                                                                                                                   |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>

</table>

For additional information about customization options, see *Translating COBOL File Descriptions* on page 2773.

**Example: Sample COBOL FD**

```cobol
01 COUNTRY-REC.
   02 G1.
      03 COUNTRY_COD1   PIC X(5).
      03 FILLER         PIC X(3).
      02 COUNTRY_NAM1   PIC X(15).
      02 FILLER         PIC X(1).
```
Standard Master File Attributes for a Millennium Data Source

For each Master File, the server must access the appropriate Millennium database ID (DBID). There are two methods for assigning the DBID to a Master File (see Specifying the Millennium DBID and TRANID on page 1382). Depending on your assignment method and on your Millennium lead transaction ID, you may need an Access File in addition to the Master File:

- Master Files describe the fields in Millennium files (see Master Files on page 1380). Master Files for Millennium file are the same as Master Files for VSAM files, except that the SUFFIX value for a Millennium file must be CPMILL for Millennium Release 3. The Master File must conform to the COBOL copybook for the file. If your site has the COBOL FD Translator feature installed, you can use it to help create a Master File. You can then edit this Master File (to change the SUFFIX value) with any text editor.

- Access Files enable you to use a lead transaction ID (TRANID) other than the default that your site established during installation (see Specifying the Millennium DBID and TRANID on page 1382). An Access File can also assign the DBID for its corresponding Master File.

When you issue a report request, the server processes the request with the following steps:

1. It locates the Master File specified by the request.
2. It examines the SUFFIX attribute in the Master File. Each Master File that describes a Millennium database must include the attribute SUFFIX=CPMILL for Millennium Release 3. When the server detects this SUFFIX, it passes control to the adapter.
3. It examines the Master File member name. If an Access File PDS has been allocated, and if it has a member with the same name as the Master File, the adapter locates that Access File.
   The adapter uses the information contained in both the Master File and the Access File (if there is one) to generate the Millennium calls required by the report request. It passes these calls to Millennium.
4. The adapter retrieves the data generated by the Millennium DBMS and returns control to the server. For some requests, the server may perform additional processing on the returned data.
Master Files

The following partial Master File illustrates how to describe a Millennium file. The numbers to the left refer to the explanatory notes that follow the sample:

1. `FILENAME=ACCTMAST, SUFFIX=CPMILL [,]$`
2. `SEGNAME=ROOT, SEGTYPE=S0,$`
3. `FILENAME=DELETE_FLAG , ALIAS= , USAGE=A1 , ACTUAL=A1 ,$
4. `GROUP=CONTRL_KEY , ALIAS=KEY , USAGE=A23 , ACTUAL=A23 ,$
   `FILENAME=CORP , ALIAS= , USAGE=A3 , ACTUAL=A3 ,$
   `FILENAME=ACCOUNT , ALIAS= , USAGE=A10 , ACTUAL=A10 ,$
   `FILENAME=COST_CENTR , ALIAS= , USAGE=A10 , ACTUAL=A10 ,$`
Note:

1. Each Master File begins with a file declaration that names the file and describes the type of data source—a Millennium file in this case. The file declaration has two attributes, FILENAME and SUFFIX.

   The FILENAME can be any one- to eight-character name that complies with server naming conventions. For documentation purposes, you can give it the same name as the Master File member name.

   SUFFIX=CPMILL indicates that Millennium Release 3 is required for data retrieval.

2. Each type of Millennium record described in a Master File requires a segment declaration consisting of at least two attributes, SEGNAME and SEGTYPE. The SEGNAME value is ROOT, and the SEGTYPE value is S0 (S zero).

3. To describe a Millennium field in the Master File, you must include a FIELD record (or, for a key field, a GROUP record) that specifies the attributes FIELDNAME, ALIAS, USAGE, and ACTUAL:

   - The FIELDNAME value is the server name for the field. Since field names appear as default column titles on reports, select names that are representative of the data. You can specify field names, aliases, or a unique truncation of either in requests.

   - The ALIAS value in the Master File is an optional alternate name for the field, except if the field is a key field.

   - The USAGE format describes how the server will display the value in reports.

   - The ACTUAL format describes how the data field exists in storage. It must conform to the COBOL FD statement for the field. See ACTUAL Format Conversion Chart for how to determine ACTUAL formats.

4. You must describe the primary key field with the GROUP attribute instead of the FIELDNAME attribute, and you must assign its alias as ALIAS=KEY.

   If the key field is composed of multiple elementary fields, describe the elementary fields directly below the GROUP record. The USAGE format of the GROUP must be alphanumeric. Its length is the sum of the server internal storage lengths for the individual fields. The ACTUAL format of the GROUP must also be alphanumeric. Its length is the sum of the subordinate field lengths.

**ACTUAL Format Conversion Chart**

The ACTUAL attribute indicates the server representation of Millennium field formats. Use the following chart as a guide for describing ACTUAL field formats:
**Standard Master File Attributes for a Millennium Data Source**

<table>

</table>

**Note:** The USAGE lengths shown are minimum values. You can make them larger and add edit options. You must allow space for all possible digits, a minus sign for negative numbers, and a decimal point in numbers with decimal digits.

**Specifying the Millennium DBID and TRANID**

**How to:**

Specify the Master File Member Name

You must assign a Millennium database ID (DBID) to each Master File. You can use either of the following techniques to assign the DBID:

- Include the DBID as the last three characters of the Master File member name. For example, if you store the Master File in member ANYGLM, its assigned DBID is GLM (General Ledger).

- Assign the DBID in an Access File. The Access File can also assign the lead transaction ID (TRANID) for its associated Master File.

Create an Access File if:

- The Master File member name does not include a DBID assignment; that is, the last three characters of the Master File member name do not identify a valid DBID.
The Master File member name assigns a DBID, but the DBID it assigns is not the one you need to access.

You need a lead transaction ID other than the default (your site establishes the default lead transaction ID during installation).

The Master File member name must either include the appropriate DBID assignment, or it must identify an Access File, or both.

**Syntax:**

**How to Specify the Master File Member Name**

```plaintext
{xxxxxdbd|anyname}
```

where:

- **xxxx**
  
  Is a name, which can be up to five characters long, that conforms to file-naming conventions.

- **dbd**
  
  Is a 3-character DBID. The adapter accesses this DBID unless an Access File member named xxxxxdbd exists and assigns a different DBID. When both the Master File member name and the Access File assign the DBID, the DBID from the Access File takes precedence.

- **anyname**
  
  Is the name of a member in the Access File data set that contains the DBID and/or lead transaction ID to use.

As an example, consider the Master File in *Master Files* on page 1380. It is member ACCTMAST in the Master File PDS, indicating that member ACCTMAST in the Access File data set contains the required DBID and/or TRANSID.

**Access Files**

If an Access File is required, the server JCL must allocate the PDS containing Access File members to DDNAME FOCPRV.

```
[DBID=dbd], [TRANID={tran|M3LL}] ,$
```

where:

- **dbd**
  
  Is the three-character Millennium DBID associated with this file. You can omit this parameter if you included the appropriate DBID as the last 3 characters of the Master File member name.
tran

Is the optional Multi:Mill lead transaction ID. M3LL is the default lead transaction ID for Millennium Release 3 unless your site chooses a different default value during installation. For more information, check with your systems support staff.

**Note:** Every Master File named in a single request (such as a join of two databases) must use the same TRANID.

The following is a sample Access File:

```plaintext
DBID=GLM,$
```

This Access File points to:

- A General Ledger file (DBID=GLM).
- The default lead transaction ID, M3LL for Millennium Release 3 (unless the site chose a different default during installation).
The Adapter for Model 204 allows applications to access Model 204 data sources. The adapter converts application requests into native Model 204 statements and returns optimized answer sets to the requesting application.

Topics:
- Preparing the Model 204 Environment
- Configuring the Adapter for Model 204
- Model 204 Overview and Mapping Considerations
- Managing Model 204 Metadata
- Master Files for Model 204
- Access Files for Model 204
- Customizing the Model 204 Environment
- Using Customized Security Exits
- Adapter Tracing for Model 204
Preparing the Model 204 Environment

Before you install the adapter, review the following list of software requirements:

- Model 204 must be installed and working. If it is not, contact your Model 204 database administrator. The adapter may be used with Model 204 Version 2.2.0 and higher.
- The server must be installed on your system. If it is not, contact your server administrator or consult the appropriate server installation guide.

Configuring the Adapter for Model 204

In this section:

- Allocating the Model 204 Libraries
- Specifying Account and File Passwords
- Testing the Adapter Installation
- Declaring Connection Attributes

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish. The Adapter for Model 204 can be configured from the Web Console or from the Data Management Console.

Allocating the Model 204 Libraries

Prior to configuring the Adapter for Model 204, you must allocate the following Model 204 libraries.

Edit the ISTART JCL:

- Allocate the Model 204 load library to ddname STEPLIB.
- Any private Master File libraries and prefix.EDAMFD.DATA should be allocated to ddname MASTER in the JCL.
- Any private Access File libraries and prefix.EDAAFD.DATA should be allocated to ddname ACCESS in the JCL.

Specifying Account and File Passwords

Your Model 204 database administrator must provide account and file security information in order for the adapter to access password protected Model 204 files or groups.
An account consists of the Model 204 user ID, an optional account name, and the associated password. You can specify these security values using the following methods:

- Set appropriate values to declare the CONNECTION attributes and then use the connection name in the Access File CONNECTION attribute.
- Include the ACCOUNT and ACCOUNTPASS attributes in the first declaration of the Access File.
- Issue the adapter M204IN SET M204ACCNT and M204PASS commands.
- Use a security exit. If you use this method, you must omit all previously mentioned sources of account information. For details, see Using Customized Security Exits on page 1434.

You must also know the file name and password (if there is one) for each Model 204 file or group you access. Specify these values with the FILE and PASS attributes in each SEGNAME declaration of the Access File.

Testing the Adapter Installation

To verify the adapter installation, run a simple query using one of the pairs of Master and Access Files you have defined for a Model 204 file.

Declaring Connection Attributes

How to:
- Declare Connection Attributes
- Declare Connection Attributes Manually

Example:
- Sample Connection Declarations

Reference:
- Connection Attributes for Model 204

In order to connect to Model 204, the adapter requires connection information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).
Procedure: **How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*.
   
   or
   
   From the Data Management Console, expand the *Adapters* folder.
   
   The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.
   
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

Reference: **Connection Attributes for Model 204**

The MODEL 204 adapter is under the *DBMS* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**Channel Name**

Is the CRAM, IUCV, or VMCF communication channel name (up to 8 characters).

**Account**

Is a string of 1-10 characters, to be used only if an account under which the user will log in to MODEL 204 must be supplied.

**Readwol**

Readwol (read without locks) instructs the adapter to issue an IFFWOL (find without locks) HLI call. To use this setting, enter ON.
If you leave the setting blank (OFF), the adapter holds locks on the appropriate records in order to ensure accurate data for reports. The locks prevent other users from updating the target records while Model 204 constructs answer sets. The adapter generates standard IFFIND calls that lock the found set in SHR mode.

**Singlethread**

There are two types (or modes) of thread management:

- **Multiple.** The adapter creates as many threads as it needs whenever they are needed to access files. This setting is recommended for performance reasons.
  
  To use the default setting (OFF), leave this option blank.

- **Single.** The adapter creates one thread for all file access; this restricts processing to one request. Single thread forces the adapter to use a single thread for all file access. For example, if a request joins 10 files, only one thread is used to access all of the files.
  
  To use this setting, enter ON.

**Missing**

You can control the display of Model 204 null data on reports. Null data is translated into the server missing data display value. The default NODATA display value is the period (.)

When the Missing option is selected, the edit specification for all IFGET calls includes an (L) format code. If Model 204 returns a zero in the first byte, the adapter considers that field to be missing. To use this setting, enter ON.

**Note:** IFFIND calls contain IS PRESENT or IS NOT PRESENT criteria only when the request includes a server IF or WHERE MISSING selection test.

If you leave this setting blank (OFF), null values are not represented on reports. (This is the default setting.)

**Note:**

- The default setting can affect the results of server DML SUM or COUNT aggregate operations. Null values may be counted or averaged in as existing values.
- You must include the Missing setting in order to specify screening conditions (IF or WHERE MISSING tests) for null values.

**Maxmbuf**

You can set or change the maximum size of all adapter buffers.
Note that Maxmbuf:

- Should be greater than the larger of two Model 204 buffer settings, LIBUFF and LOBUFF. To identify which buffer is larger, check the parameters in the Model 204 start-up procedure or use the adapter Trace Facility (SET TRACEON=M204IN) to display the settings.

- Should be equal to the size of the largest segment in the Master File if the segment size is greater than the Model 204 LIBUFF and LOBUFF buffer settings. Having the maximum buffer size equal to that of the largest segment prevents S0C4 ABEND conditions.

Enter:

\[ nnnn \]

To represent the maximum size in bytes. (For example, specify 4096 for a MAXMBUFF value of 4K.) There is no default value.

**Ftblsize**

The Ftblsize options enables you to control the size of the Model 204 FTBL buffer. The LFTBL parameter, specified in the Model 204 start-up procedure, governs the size of the FTBL buffer.

Enter:

\[ nnnn \]

To represent the FTBL size in bytes. (For example, specify 4096 for an FTBL value of 4K.)

You should set FTBL to a value larger than the previously defined Model 204 LFTBL value.

**User**

Is the user ID (1-10 characters) by which you are known to MODEL 204. If omitted, other sources of this data will be used (that is, file level information from the Access File or a security exit).

**Password**

Is the password associated with the user ID. If omitted, other sources of this data will be used (that is, file level information from the Access File or a security exit)

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.
If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:**

**How to Declare Connection Attributes Manually**

```sql
ENGINE M204INX SET CONNECTION_ATTRIBUTES connection_name
channel_name/_userid_password:
"[ACCOUNT account] [READWOL {ON|OFF}] [SINGLETHREAD {ON|OFF}]
[MISSING {ON|OFF}] [MAXMBUF nnnnn] [FTBL.SIZE nnnnn]"
```

where:

- **connection_name**
  Is the name of the current connection.

- **channel_name**
  Is the CRAM, IUCV, or VMCF communication channel name (up to 8 characters).

- **userid,password**
  Are valid M204 user IDs and passwords. If they are omitted then other sources of this data will be used (that is, file level information from the Access File or a security exit).

- **account**
  Is a string of 1-10 characters, to be used only if an account under which the user will log in to Model 204 must be supplied.

  A space is used as the delimiter between the parameters and values.

**READWOL**

The options are:

- **ON** instructs the adapter read without locks and issue an IFFWOL (find without locks) HLI call.

- **OFF** holds locks on the appropriate records to ensure accurate data for reports. The locks prevent other users from updating the target records while Model 204 constructs answer sets. The adapter generates standard IFFIND calls that lock the found set in SHR mode. (This is the default setting.)

**SINGLETHREAD**

The options are:
**Configuring the Adapter for Model 204**

- **ON** is used for single thread processing. With this setting, the adapter creates one thread for all file access; this restricts processing to one request. For example, if a request joins 10 files, only one thread is used to access all of the files.

- **OFF** is used for multiple thread processing. With this setting, the adapter creates as many threads as it needs whenever they are needed to access files. OFF, the default setting, is recommended for performance reasons.

**MISSING**

You can control the display of Model 204 null data on reports. Null data is translated into the server missing data display value. The default NODATA display value is the period (.).

The options are:

- **ON** where in this setting, the edit specification for all IFGET calls includes an (L) format code. If Model 204 returns a zero in the first byte, the adapter considers that field to be missing.

  Note that IFFIND calls contain IS PRESENT or IS NOT PRESENT criteria only when the request includes a server IF or WHERE MISSING selection test.

- **OFF** where in this setting, null values are not represented on reports. This is the default setting.

  **Note:** The default setting can affect the results of server DML SUM or COUNT aggregate operations. Null values may be counted or averaged in as existing values.

  You must include the Missing setting in order to specify screening conditions (IF or WHERE MISSING tests) for null values.

**MAXMBUF**

You can set or change the maximum size of all adapter buffers.

- **nnnn** represents the maximum size in bytes. (For example, specify 4096 for a MAXMBUFF value of 4K.) There is no default value.

  Note that MAXMBUF:

  - Should be greater than the larger of two Model 204 buffer settings, LIBUFF and LOBUFF. To identify which buffer is larger, check the parameters in the Model 204 start-up procedure or use the adapter Trace Facility (SET TRACEON=M204IN) to display the settings.
Should be equal to the size of the largest segment in the Master File if the segment size is greater than the Model 204 LIBUFF and LOBUFF buffer settings. Having the maximum buffer size equal to that of the largest segment prevents S0C4 ABEND conditions.

**FTBLSIZE**

The FTBLSIZE options enables you to control the size of the Model 204 FTBL buffer. The LFTBL parameter, specified in the Model 204 start-up procedure, governs the size of the FTBL buffer.

$n_n_n_n$ represents the FTBL size in bytes. (For example, specify 4096 for an FTBL value of 4K.)

Note that you should set FTBL to a value larger than the previously defined Model 204 LFTBL value.

Any of the environmental SET commands in the prior version of Model 204 may be used, except M204ACCNT and M204PASS.

**Example:**  
**Sample Connection Declarations**

```plaintext
ENGINE M204INX SET CONNECTION_ATTRIBUTES m204a IFAMCHNL/user1, pwd1: "ACCOUNT acc1 MISSING ON READWOL ON FTBLSIZE 16000"

ENGINE M204INX SET CONNECTION_ATTRIBUTES m204b IFAMCHNL/user2, pwd2: "SINGLETHREAD ON"

The command ? SET may point to a valid connection_name. For example:

ENGINE M204INX SET CONNECTION_ATTRIBUTES M204 IFAMSUPT/SUPERKLUGE,PIGFLOUR: "ACCOUNT ACT1 MISSING ON"

ENGINE M204INX ? SET
(FOC4855) Set M204ACCNT option
(FOC4856) Set M204PASS option
(FOC4857) Set SINGLETHREAD option : OFF
(FOC4858) Set READWOL option : OFF
(FOC4859) Set MISSING option : OFF
(FOC4860) Set MAXMBUFF option
(FOC4861) Set FTBLSIZE option

ENGINE M204INX ? SET M204
(FOC4863) Set IFAMCHNL option : IFAMSUPT
(FOC4855) Set M204ACCNT option : SUPERKLUGE ACT1
(FOC4856) Set M204PASS option : PIGFLOUR
(FOC4857) Set SINGLETHREAD option : OFF
(FOC4858) Set READWOL option : OFF
(FOC4859) Set MISSING option : ON
(FOC4860) Set MAXMBUFF option : 0
(FOC4861) Set FTBLSIZE option : 0
```
Model 204 Overview and Mapping Considerations

In this section:
- Files With One Logical Record Type
- Files With Multiply Occurring Fields
- Describing Files to the Server
- Mapping Model 204 and Server Relationships
- Dynamic Joins
- Embedded Joins
- Joining Unrelated Files
- Summary of Mapping Rules

A Model 204 file can represent one file or a collection of files called a group. A single Model 204 file can contain records that vary in length and format; a record can consist of fields that also vary in length. Fields are the smallest elements or units of data. They can occur more than once per record. A unit of records with identical sets of fields is called a logical record type. A Model 204 file is defined in a Model 204 file description.

In the sections that follow, you will notice that:

- A Model 204 field is equivalent to a server Master File field.
- A logical record type corresponds to a server Master File segment. The individual record corresponds to a segment instance.
- Model 204 fields that appear more than once in a record map to a server Master File OCCURS segment.
- One or more record types can be described in any order in a pair of Master and Access Files.
- One or more Model 204 files can be described in a pair of Master and Access Files.

Files With One Logical Record Type

A Model 204 file that contains records with identical sets of fields (the same logical record type) can be represented as a single Master File segment. Each Model 204 field that occurs only once becomes a Master File field. The ALIAS attribute in the Master File identifies the Model 204 field name.
In the Master File, describe the logical record type as a segment. The segment description can include some or all of the Model 204 fields in any order. The corresponding Access File identifies the record type's Model 204 file or group name and its password; the Access File can also include FIELD declarations that specify a TYPE attribute to indicate the appropriate suffix operators for Model 204 key fields. Master File field suffix operators (for example, KEY) identify different types of Model 204 key fields.

**Note:** A Model 204 field that can occur more than once should be represented as a separate OCCURS segment.

1. Is one Model 204 file with one logical record type.

2. Is the equivalent server Master File segment. The Master File field VVIN represents the Model 204 field VIN.

**Files With Multiply Occurring Fields**

In Model 204 files, some fields may appear more than once per record. Represent each multiply occurring field separately from the non-repeating fields as a server Master File OCCURS segment. In this case, the Master File contains a parent segment to describe all the non-repeating fields, and a separate dependent OCCURS segment for each multiply occurring field.

When you create a Master File, describe the OCCURS segment only if you need the multiply occurring field for your reports. You are not required to describe every multiply occurring field. Do not describe the OCCURS segment in the corresponding Access File unless its size exceeds the buffer capacity, a situation that is explained in *Customizing the Model 204 Environment* on page 1429.
Describing Files to the Server

The following diagram illustrates one multiply occurring field and its equivalent OCCURS segment:

1. Is the Model 204 VEHICLES file with one logical record type and one multiply occurring field called OTHER DRIVER that identifies drivers besides the principal driver.

2. Is the equivalent multi-segment server structure. The parent (or root, in this case) is the VEHICLE segment; it contains all of the non-repeating fields. The dependent segment is the OCCURS segment which contains iterations of the Model 204 OTHER DRIVER field. In the Master File, the segment declaration for the dependent segment must include the OCCURS attribute.

If a Model 204 file contains multiple logical record types, each logical record type corresponds to one segment. You can represent a Model 204 file with several logical record types either:

- As a multi-segment server Master File structure with a hierarchical retrieval path. The segments are cross-referenced by Embedded Joins defined on the parent/child relationships.

- As several individual segments, each described in a separate pair of Master and Access Files.

In a multi-segment Master File, you can include segment descriptions for all of the logical record types or only those you need for your reports. To identify the parent of a dependent segment, specify the PARENT attribute in the segment declaration of the dependent segment.

In the corresponding Access File, for each logical record type you must specify the:

- Model 204 file and password.
Model 204 record type field and the unique value that identifies it.

- Shared field that implements the Join relationship.

- Model 204 key fields (TYPE attributes in FIELD declarations identify the appropriate suffix operators).

**Note:** Record type fields identify individual record types that reside in the same Model 204 file. Model 204 files that consist of one logical record type do not require record type fields. In the Access File, the RECTYPE and RECTVAL attributes specify record type fields and the values.

**Mapping Model 204 and Server Relationships**

In Model 204, interfile relationships are not coded in the Model 204 file description. This provides a certain degree of flexibility because the Model 204 files can be cross-referenced dynamically. On the other hand, the burden of connecting the Model 204 files falls on the user.

Model 204 relationships between logical record types are cross-referenced using shared key fields. The adapter supports this implementation. You can logically join Model 204 files using the adapter with either of the following techniques:

- Issue JOIN commands to dynamically join the Model 204 files.
- Create a multi-segment server Master File structure and describe the Join relationships in a pair of Master and Access Files (this multi-segment structure is also called an Embedded Join or Server View).

Both techniques are described in the following sections.

**Dynamic Joins**

If there is a shared or common field, you can use the server JOIN command to dynamically Join:

- Separate physical Model 204 files that each contain one logical record type. These Model 204 files are usually described as single segment Master Files.

- Logical record types that are described to the server as single segment Master Files, but that originate from the same Model 204 file.

- Multi-segment server structures that represent several Model 204 files and/or different record types from the same Model 204 file. Multi-segment Master Files are explained in *Embedded Joins* on page 1399.
The following diagram illustrates a Model 204 Join and its equivalent Server Join:

1. Are two Model 204 files, VEHICLES and CLIENTS. Each file contains one logical record type for this example. The common or key field is VIN.

2. Are two equivalent server segments. Each segment is described in a separate pair of Master and Access Files. The field names for the common field are VEHICLE_IDENIFICATION_NUMBER and VVIN. The Model 204 key fields are specified with the TYPE=KEY attribute in the Access File.

The JOIN command includes the names of the Master Files and the common field names. To retrieve data from the joined structure, issue a report request that specifies the host (or parent) Master File from the JOIN command.

**Note:** Since in this example each Model 204 file consists of one logical record type, record type fields are not specified in the Access Files.
The following diagram illustrates a Model 204 file with two record types and the Server Join:

1. Is the Model 204 CLIENTS file containing two logical record types. The common or key field is POLICY NO. The RECTYPE field contains the value POLICYHOLDER for the HOLDER record type and the value DRIVER for the DRIVER record type.

2. Are two equivalent Master File segments. Each segment is described in a separate pair of Master and Access Files. The field names for the common field are POLICY_NUMBER and DRIVER_POLICY_NUMBER. The Model 204 key fields are specified with the TYPE=KEY attribute in the Access File. Since both record types reside in the same Model 204 file, each Access File segment declaration also includes RECTYPE (record type) and RECTVAL (record type value) attributes.

The JOIN command includes the names of the Master Files and the common field names. To retrieve data from the joined structure, issue a report request that specifies the host (or parent) Master File from the JOIN command.

**Embedded Joins**

You can also implement Join relationships by describing a multi-segment FOCUS structure in a single pair of Master and Access Files. If there is a shared or common field, you can create an Embedded Join for:

- Separate physical Model 204 files that each contain one logical record type. The Model 204 files are described as segments in the multi-segment structure.
Logical record types that originate from the same Model 204 file. These record types are described as segments in the multi-segment structure. In the Access File, the RECTYPE and RECTVAL attributes in each segment record identify the record type field and its corresponding value.

Other multi-segment FOCUS structures. A Master File might relate two hierarchical structures as one. For example, the AUTO Master File might incorporate the VEHICLE and CLIENT Master Files.

Embedded Joins offer two advantages:

- They create a logical FOCUS view of the record types. The view may also provide a measure of security by limiting access to segments or fields.
- You do not have to issue an explicit JOIN command.

When you create a Master File, describe the Model 204 logical record types or files as a hierarchy. Start first by choosing a record type or file to be the root segment. The root segment has dependent segments which, in turn, may have dependent segments. The dependent segments identify the superiors (or parents) with the PARENT attribute. Any record type can act as a dependent provided that its shared field is a key field.

In the associated Access File, for each pair of related segments, specify the shared field from the parent and dependent segments with the KEYFLD and IXFLD attributes. The Interface implements the relationship by matching values at run time.

The Embedded Join is executed automatically when you issue a report request that references fields from two related segments. You do not specify the shared field in your report request; the selection of the shared field is transparent.

**Note:** It is possible to join unrelated Model 204 files and record types that do not have common fields by describing a DUMMY segment.
The following diagram illustrates an Embedded Join for two Model 204 files:

1. Are two Model 204 files, VEHICLES and CLIENTS. Each file contains one logical record type for this example. Since they exist as physically separate files, they do not contain a Model 204 record type field. The common or key field is VIN.

2. Are two equivalent FOCUS segments described in one pair of Master and Access Files. The field names for the common field are VEHICLE IDENTIFICATION NUMBER and VVIN. The Model 204 key fields are specified with the TYPE=KEY attribute in the Access File.

To create a parent/child relationship, describe the HOLDER segment as the parent (or root) and the VEHICLE segment as the dependent in the Master File. Include the PARENT=HOLDER attribute in the segment declaration for VEHICLE. In the Access File, specify the KEYFLD and IXFLD attributes to create the Embedded Join.
The following diagram illustrates an Embedded Join for a Model 204 file with two record types:

1. Is the Model 204 CLIENTS file containing two logical record types. The common or key field is POLICY NO. The RECTYPE field contains the value POLICYHOLDER for the HOLDER record type and the value DRIVER for the DRIVER record type.

2. Are two equivalent FOCUS segments described in one pair of Master and Access Files. The field names for the common field are POLICY_NUMBER and DRIVER_POLICY_NUMBER. The Model 204 key fields are specified with the TYPE=KEY attribute in the Access File. Since both record types reside in the same Model 204 file, the Access File segment declarations also include the RECTYPE (record type) and RECTVAL (record type value) attributes.

To create a parent/child relationship, describe the HOLDER segment as the parent (or root) and the DRIVER segment as the dependent in the Master File. Include the PARENT=HOLDER attribute in the segment declaration for DRIVER. In the Access File, specify the KEYFLD and IXFLD attributes in the DRIVER segment declaration to create the Embedded Join.

### Joining Unrelated Files

You can describe unrelated Model 204 files or logical record types as Embedded Joins even if a shared field does not exist. To do so, describe a special dummy segment (SEGNAME=DUMMY) as the root in the Master File. Then, specify the unrelated segments as parallel dependents of the dummy root. Since the dummy segment is a virtual segment, do not describe fields for it in the Master File, and do not include a corresponding segment declaration for it in the Access File.
If your report request includes fields from two or more segments, FOCUS makes only one retrieval pass over the answer set returned by the Model 204 DBMS. Fields specified for sort phrases (BY and ACROSS) and screening tests (IF and WHERE) must lie on the same retrieval path as the other requested fields. You cannot use a field from one unrelated segment to sort the data in other segments.

The following diagram illustrates two Model 204 files, the CLIENTS file and the VEHICLES file. These two files are joined using a FOCUS dummy segment:

1. Are two Model 204 files, CLIENTS and VEHICLES. The record type field in the DRIVER segment identifies all client records that have the value 'DRIVER'. A dummy segment is needed because there is no shared field to cross-reference or join these files.

2. Is an equivalent multi-segment FOCUS structure. The root is a DUMMY segment. The two dependents are related to the root. They are not related to each other because a common field does not exist.

To create a Master File for this structure, specify the segment declaration for the dummy segment (SEGNAME=DUMMY) first, so it functions as the root. Do not describe fields for it. Then, describe the dependent segments, and include the PARENT=DUMMY attribute to identify the dummy segment as the parent. In the associated Access File, do not specify a segment declaration for the dummy segment; include segment declarations only for the dependent segments. The record type field is required in the DRIVER segment since the DRIVER segment comes from a Model 204 file, CLIENTS, that contains two logical record types. Do not specify KEYFLD/IXFLD values.
Summary of Mapping Rules

Model 204 and FOCUS use similar elements:

<table>
<thead>
<tr>
<th>Model 204 Entities</th>
<th>FOCUS Entities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model 204 field</td>
<td>FOCUS field</td>
</tr>
<tr>
<td>Logical record type</td>
<td>FOCUS segment</td>
</tr>
<tr>
<td>Individual record</td>
<td>Segment instance</td>
</tr>
<tr>
<td>Model 204 file with one record type</td>
<td>FOCUS segment</td>
</tr>
<tr>
<td>Multiply-occurring Model 204 fields in a record</td>
<td>FOCUS OCCURS segment</td>
</tr>
</tbody>
</table>

Some general rules for describing Model 204 files are:

- Each logical record type becomes a FOCUS segment. A FOCUS segment may represent an entire Model 204 file (with one logical record type) or one logical record type from a Model 204 file with several record types.

- A Model 204 file containing two or more logical record types must have a record type field to identify each record type.

- A Model 204 file containing one logical record type does not require a record type field; the Model 204 file may contain an optional one.

- Relationships can be implemented with the JOIN command or by describing Embedded Joins in the FOCUS file descriptions. The maximum number of Model 204 files or logical record types that can be related is 64 for Embedded Joins and 16 for Dynamic Joins.

Managing Model 204 Metadata

In this section:
Creating Synonyms

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Model 204 data types.

The logical description of a Model 204 file is stored in a Master File, which describes the field layout. The physical attributes of the Model 204 file, such as the keys description, occurring data access, and security are stored in the Access File.
Creating Synonyms

How to:
Create a Synonym

Example:
Creating a Synonym

Reference:
Synonym Creation Parameters for Model 204
Managing Synonyms

Synonyms define unique names (or aliases) for each Model 204 table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File, which represent the server metadata.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

   The synonym is created and added under the specified application directory.
**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting **Create Synonym**.
- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference: Synonym Creation Parameters for Model 204**

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the **Create Synonym** button, which generates the synonym based on your entries.

- **File name**
  - Is the Model 204 file name.

- **File password**
  - Is the associated password for the file. This entry is optional.

- **Rectype name**
  - Is a valid Model 204 field with the name RECTYPE. This entry is optional.

- **Rectype value**
  - Is a valid value of the Model 204 field with the name RECTYPE. This entry is optional.

- **Synonym name**
  - Displays the name that will be assigned to the synonyms. To assign a different name, replace the displayed value.

- **Application**
  - Select an application directory. The default value is baseapp.

- **Prefix/Suffix**
  - If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

  - If all tables and views have unique names, leave the prefix and suffix fields blank.
**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**Example:** **Creating a Synonym**

To generate a synonym for the VEHICLES data source, enter the following information on the Create Synonym panes of the Web Console or the Data Management Console:

1. On the first Create Synonym pane, enter VEHICLES in the File Name field and WHEELS in the File Password field.
2. Enter *m204veh* as the Synonym name.
3. Select *m204* from the Application list.
4. Click *Create Synonym*. The synonym is created and added under the specified application directory (baseapp is the default).
5. The Create Synonym Status pane indicates that the synonym was created successfully. Click *Applications* on the menu bar.
6. Open the *baseapp* application folder in the navigation pane and click the synonym *m204*.
7. Choose *Edit as Text* from the menu to view (and edit) the generated Master File and Access File.
Generated Master File:
FILENAME=M204VEH, SUFFIX=M204INX, $
SEGMENT=VEHICLES, SEGTYPE=S0, $
  FIELDNAME=BODY, ALIAS=BODY, USAGE=A4, ACTUAL=A4, $

  FIELD=VIN, TYPE=ORA,
M204 fields may have KEY and ORDERED attributes at the same time. In such cases, the field in the Access File has TYPE=KEY (IVK for invisible field) and a comment with information about another possible TYPE:

```
SEGNAM=RNG, CONNECTION=M204, FILE=RNG, $
FIELD=FKEY, TYPE=KEY, ATTRIBUTE=FRV, $
FIELD=FORC, TYPE=KEY, $
$  Field has KEY and ORC attributes. KEY is chosen.  $
FIELD=FORN, TYPE=KEY, $
$  Field has KEY and ORN attributes. KEY is chosen.  $
FIELD=FRNG, TYPE=RNG, $
```

**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. Note: To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. Note: This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>

Master Files for Model 204

In this section:
- SEGNAME
- SEGTYPE
- PARENT
- FIELDNAME
- ALIAS
- USAGE
- ACTUAL

How to:
- Declare File Attributes
- Declare Segment Attributes

A Model 204 file consists of records and fields. It can represent one file or a collection of files called a group. If records have identical sets of fields, the unit of records is called a logical record type. A logical record type is described as a single segment in the Master File.

A Master File consists of file, segment, and field declarations. Rules for declarations are:

- Each declaration must begin on a separate line and be terminated by a comma and dollar sign (,$). Text appearing after the comma and dollar sign is treated as a comment.
- A declaration can span as many lines as necessary as long as no attribute=value pair is separated. Commas separate attribute=value pairs.
- Certain attributes are required; the rest are optional.

The following sections summarize the syntax for each type of declaration and then present detailed explanations for each attribute.

Syntax: How to Declare File Attributes

Each Master File begins with a file declaration that names the file and describes the type of data source, a Model 204 file or group in this case. The file declaration has two attributes, FILENAME and SUFFIX:

```plaintext
FILENAME=name, SUFFIX=M204IN [,,$]
```
where:

*name*

Is a 1- to 8-character name that identifies the Master File. The name must comply with server file naming conventions.

*M204IN*

Is the SUFFIX value that specifies the Adapter for Model 204.

**Syntax:**  
How to Declare Segment Attributes

Each logical record type described in a Master File requires a segment declaration that consists of at least two attributes, SEGNAME and SEGTYPE

```
SEGNAME={name|DUMMY}, SEGTYPE={S0|U} [, PARENT=parent] $,
```

where:

*name*

Is a 1- to 8-character name that identifies the segment. The value DUMMY creates a virtual segment used for joining unrelated segments.

*S0*

Indicates to the adapter that the Model 204 DBMS handles the storage order of the data. S0 is the default setting.

*parent*

For multi-segment structures (Embedded Joins) only, is the SEGNAME value for the parent record type. This attribute is required in segment declarations that describe dependent segments.

**SEGNAME**

The SEGNAME (or SEGMENT) attribute identifies each Model 204 logical record type. The SEGNAME value can be a maximum of 8 alphanumeric characters. It may be the name of the record type or an arbitrary name and must be unique within a Master File.

The SEGNAME value from the Master File is also specified in the Access File where the segment declaration identifies the name of the Model 204 file. In this manner, the SEGNAME value serves as a link to the actual Model 204 file name.

**SEGTYPE**

In a single segment Master File, the SEGTYPE value is S0. The Model 204 DBMS handles the storage order of the data.
In a multi-segment Master File, SEGTYPE values for dependent segment declarations can be S0 or U (for unique).

- SEGTYPE=S0 indicates that the dependent record type has a one-to-many or many-to-many relationship with the record type named as its parent. For every record of the parent record type, there may be more than one record in the dependent record type.

- SEGTYPE=U indicates that the dependent record type has a one-to-one or a many-to-one relationship with the record type named as its parent. For every record of the parent record type, there may be (at most) one record in the dependent record type. For a one-to-one relationship to exist, both record types must share a common key. For a many-to-one relationship to exist, the common key of the dependent record type must be a subset of the common key of the parent record type.

If the SEGTYPE attribute is omitted from any segment record in the Master File, its value defaults to S0.

**PARENT**

**How to:**
Declare Field Attributes

The PARENT attribute is required in dependent segment declarations. Its value is the SEGNAME value of the dependent record type’s parent (the logical record type to which it will be related at run time).

**Syntax:** **How to Declare Field Attributes**

Each record in a logical record type consists of one or more fields. These Model 204 fields are described in the Master File with the primary attributes FIELDNAME, ALIAS, USAGE, and ACTUAL. You are only required to describe Model 204 fields you use in reports, and you can specify them in any order within each segment.

`FIELD[NAME]=field, [ALIAS=] [m204field], [USAGE=]display, [ACTUAL=]An ,$`

where:

- `field`
  Is a 1- to 66-character field name. In requests, the field name can be qualified with the Master File and/or segment name. Although the qualifiers and qualification characters do not appear in the Master File, they count toward the 66 character maximum.

- `m204field`
  Is the Model 204 field name, which can be up to 66 characters (or, optionally left blank if the field name exceeds 66 characters and is described in the Access File).
**display**

Is the server display format for the field.

An

Is the server definition of the Model 204 field format and length ($n$).

You can omit the ALIAS, USAGE, and ACTUAL keywords from the field declaration if the values are specified in the standard order (FIELD, ALIAS, USAGE, ACTUAL). For example, the following declarations are equivalent:

```
FIELD = YEAR, ALIAS=YEAR, USAGE=A2, ACTUAL=A2,$
FIELD = YEAR, YEAR, A2, A2,$
```

**FIELDNAME**

Field names must be unique within the Master File and may consist of up to 66 alphanumeric characters. Model 204 field names are acceptable values if they meet the following naming conventions:

- Names can consist of letters, digits, and underscore characters. Special characters and embedded blanks are not advised.

- The name must contain at least one letter.

Since the field name appears as the default column title for reports, select a name that is representative of the data. You can specify field names, aliases, or a unique truncation of either in requests.

Duplicate field names (the same field names and aliases) within a segment are not permitted. Requests can qualify duplicate field names from different segments with the name of the Master File and/or segment.

**Note:** Field names specified in OCCURS segments may not be qualified.

**ALIAS**

The ALIAS value for each field must be the full Model 204 field name; the adapter uses it to generate HLI calls. The ALIAS name must be unique within the segment. If the name is longer than the 66 character maximum, leave the ALIAS attribute blank in the Master File and specify the alias in the Access File instead. The ALIAS name must comply with the field naming conventions listed previously. If the Model 204 field name contains an embedded blank, enclose the name in single quotation marks.

Aliases may be duplicated within the Master File if they are defined for different Model 204 logical record types. However, the corresponding field names must be unique. For example, the ALIAS values for two Model 204 record type fields may be RECTYPE, but the field names must be unique.
Note: Do not use RECTYPE as a field name.

**USAGE**

The USAGE attribute indicates the display format of the field. An acceptable value must include the field type and length and may contain edit options. The server uses the USAGE format for data display on reports. All standard server USAGE formats (A, D, F, I, P) are available.

**ACTUAL**

**How to:**

Declare OCCURS Attributes
Track a Sequence Within Multiply Occurring Fields

The ACTUAL attribute indicates the server representation of Model 204 field formats as returned by the Model 204 DBMS in the data buffer. Specify an alphanumeric format (A) with a length (n) equal to the maximum length for the Model 204 field. If the ACTUAL length is less than the maximum length for the Model 204 field, field values will be truncated.

**Note:** Since Model 204 file descriptions do not define field lengths, ask your Model 204 database administrator or consult other sources, such as data dictionaries, for field information.

**Syntax:**

**How to Declare OCCURS Attributes**

Describe each multiply occurring field that exists in a Model 204 record as an OCCURS segment. The segment declaration for an OCCURS segment consists of the SEGNAME, PARENT, and OCCURS attributes. It contains one field declaration to represent the multiply occurring field, and, optionally, a field declaration for an internal counter, the ORDER field. Each OCCURS segment is described as a dependent segment. Its parent segment describes all non-repeating fields from the logical record type. You do not have to describe an OCCURS segment if you do not plan to use the multiply occurring field in report requests.

```plaintext
SEGNAME=segname, PARENT=parentname, OCCURS=VARIABLE,$
```

where:

- **segname**
  - Is the 1- to 8-character name of the OCCURS segment.

- **parentname**
  - Is the SEGNAME value of the parent segment that contains the non-repeating fields from the logical record type.
**VARIABLE**

Indicates that the number of occurrences varies.

**Note:**

- The SEGTYPE attribute is always S0 for OCCURS segments and, therefore, can be omitted.
- OCCURS segments generally do not require corresponding segment declarations in the Access File. An exception is for processing OCCURS segments that exceed the buffer capacity.
- Field names in OCCURS segments may not be qualified with Master File or segment names, but the TYPE attribute can define suffix operators in the Access File.

**Syntax:** **How to Track a Sequence Within Multiply Occurring Fields**

The ORDER field is an optional counter that you can define to identify the sequence number of each multiply occurring field when the order of data is significant. You can use its value in subsequent report requests. The ORDER field does not represent an existing Model 204 field; it is used only for internal processing. The ORDER field must be the last field described in the OCCURS segment

```
FIELD=name, ALIAS=ORDER, USAGE=In, ACTUAL=I4,$
```

where:

- **name**
  
  Is any meaningful name.

- **ALIAS**
  
  Must be ORDER.

- **USAGE**
  
  Is an integer (In) format.

- **ACTUAL**
  
  Must be I4.
The following annotated example illustrates an OCCURS segment in the VEHICLE Master File.

1. SEGNAME=VEHICLE,$
   FIELD=VVIN ,ALIAS=VIN ,A10 ,A10 ,$
   FIELD=YEAR ,ALIAS=YEAR ,A2 ,A2 ,$
   FIELD=MAKE ,ALIAS=MAKE ,A16 ,A16 ,$
2. SEGNAME=XOTHDR, PARENT=VEHICLE, OCCURS=VARIABLE ,$
3. FIELD=OTHER_DRIVERS, ALIAS='OTHER DRIVER' ,A6 ,A6 ,$
4. FIELD=DRVCNT, ALIAS=ORDER ,I4 ,I4 ,$

Notice that:

1. Is the segment declaration for the parent segment, VEHICLE.
2. Is the OCCURS segment declaration.
3. Is the field declaration for the multiply occurring field. Field qualifiers (Master File and segment names) are not permitted, but the TYPE attribute can define a suffix operator in the Access File.
4. Is the field declaration for the ORDER field. As an internal counter field, it does not correspond to a Model 204 field.
Each Master File for a Model 204 file must have a corresponding Access File. The name of the Access File must be the same as that of the Master File. In z/OS, the Access File PDS is allocated to ddname ACCESS in the server JCL. The Access File associates a segment in the Master File with the Model 204 logical record type it describes.

The Access File consists of account, segment, and field declarations. The Access File minimally identifies account and segment information and field suffix operators. It can also contain field declarations for aliases that exceed 66 characters.

In multi-segment structures, the Access File must contain a segment declaration for each logical record type described in the Master File. Segment information may include Embedded Joins and Model 204 record type fields. The order of segment declarations in the Access File must correspond to the order in the Master File.

The Access File consists of 80 character declarations in comma-delimited format. Rules for declarations are:

- Each declaration must begin on a separate line and be terminated by a comma and dollar sign (, $).
- A declaration can span as many lines as necessary as long as no attribute=value pair is separated. Commas separate attribute=value pairs.
Blank lines and leading or trailing blanks around attribute=value pairs are ignored.

Declarations starting with an asterisk (*) in Column 1 are treated as comments.

Values that contain commas, equal signs, dollar signs, or embedded blanks must be enclosed in single quotation marks.

If you wish, you can number the declarations in columns 73 through 80.

For example, the VEHICLE Access File contains one segment declaration because the VEHICLE Master File contains only one logical record type.

```plaintext
FILE=VEHICLE1, SUFFIX=M204IN

SEGNAME=VEHICLE, $
FIELD=VIN, ALIAS=VIN, A10, A10, $
FIELD=YEAR, ALIAS=YEAR, A2, A2, $
FIELD=MAKE, ALIAS=MAKE, A16, A16, $
FIELD=MODEL, ALIAS=MODEL, A12, A12, $
FIELD=BODY, ALIAS=BODY, A4, A4, $
FIELD=COLOR, ALIAS=COLOR, A10, A10, $
FIELD=VEHICLE_PREMIUM, ALIAS='VEHICLE PREMIUM', A8, A8, $
FIELD=COLLISION_PREMIUM, ALIAS='COLLISION PREMIUM', A6, A6, $
FIELD=LIABILITY_PREMIUM, ALIAS='LIABILITY PREMIUM', A12, A12, $
FIELD=LIABILITY_LIMIT, ALIAS='LIABILITY LIMIT', A3, A3, $
FIELD=DEDUCTIBLE, ALIAS='DEDUCTIBLE', A3, A3, $
FIELD=GARAGE_LOCATION, ALIAS='GARAGING LOCATION', A12, A12, $
FIELD=TRANS, ALIAS=TRANS, A2, A2, $
FIELD=USAGE, ALIAS=USAGE, A12, A12, $
FIELD=VEHICLE_USAGE_CLASS, ALIAS='VEHICLE USE CLASS', A2, A2, $
FIELD=VEHICLE_RATING, ALIAS='VEHICLE RATING', A1, A1, $
FIELD=OWNER_POLICY, ALIAS='OWNER POLICY', A6, A6, $
FIELD=PRINCIPLE_DRIVER, ALIAS='PRINCIPLE DRIVER', A12, A12, $

SEGNAME=XOTHDR, PARENT=VEHICLE, OCCURS=VARIABLE, $
FIELD=OTHER_DRIVERS, ALIAS='OTHER DRIVER', A6, A6, $
FIELD=DRVCNT, ALIAS=ORDER, A14, A14, $
```

The following sections summarize the syntax for each type of declaration and provide detailed explanations for each attribute.

**Reference:** Access File Attributes

The following chart lists Access File attributes generated during synonym creation. Note that attributes vary depending on whether the synonym is generated based on a user requirements table or a connection string.
### Syntax: How to Enter an Account Declaration

The account declaration indicates authorization to access Model 204 files. At most, one account declaration is required; if included, it must be the first declaration in the Access File.

```
[[ACCOUNT=userid[account], ACCOUNTPASS=password, ] IFAMCHNL=channel ,$]
```

where:

- **userid**
  
  Is the user ID of 1-10 characters by which you are known to Model 204.

- **account**
  
  Is a string of 1-10 characters to be used only if an account under which the user will log in to Model 204 must be supplied.

- **password**
  
  Is the 1- to 16-character password for the account.

- **channel**
  
  Is the 1- to 8-character site specific CRAM channel name. The default is IFAMPROD for z/OS.

### Reference: ACCOUNT and ACCOUNTPASS Attributes

The ACCOUNT and ACCOUNTPASS attributes describe Model 204 accounts, user IDs, and passwords. They protect Model 204 files from unauthorized access. The account must have authorization to read the Model 204 file or group.
You can omit the ACCOUNT and ACCOUNTPASS attributes from the declaration if you:

- Use the attribute CONNECTION in the segment declaration of the Access File.
- Specify the values with the adapter M204IN SET M204ACCNT and M204PASS commands. These SET commands also enable you to change ACCOUNT and ACCOUNTPASS values during the session. For information about adapter SET commands, see *Customizing the Model 204 Environment* on page 1429.

**Reference: IFAMCHNL Attribute**

The IFAMCHNL attribute describes the CRAM channel name for z/OS. You must specify the CRAM channel if more than one ONLINE or IFAM2 job is running or if the CRAM channel name is not IFAMPROD. For the channel name used at your site, check with your Model 204 database administrator or the IFAM2 systems support staff.

If the attribute CONNECTION is provided in the segment declaration, the channel name is taken from the appropriate SET CONNECTION_ATTRIBUTES command.

**Syntax: How to Enter a Segment Declaration**

The segment declaration in the Access File establishes the link between the server Master File and the Model 204 file or group. Attributes that constitute the segment declaration are: SEGNAME, FILE, PASS, CONNECTION, KEYFLD, IXFLD, RECTYPE, RECTVAL, and ACCESS. Values for SEGNAME, FILE, and PASS are required. The attributes KEYFLD and IXFLD apply to multi-segment structures. The ACCESS attribute applies to OCCURS segments.

```
SEGNAME=name, FILE=m204file, PASS=password [,CONNECTION=connection_name] [,KEYFLD=pfield] [,IXFLD=cfield] [,RECTYPE=rtfield] [,RECTVAL=rtvalue], ACCESS={ALL|nnnn/[xxx]|AUTO/[xxx]}
```

where:

- **name**
  
  Is the SEGNAME value from the Master File.

- **m204file**
  
  Is the 1- to 8-character name for the Model 204 file.

- **password**
  
  Is the 1- to 8-character read password for the Model 204 file. The value can be blank if a password does not exist.

- **connection_name**
  
  Is the valid connection that was previously set by the SET CONNECTION_ATTRIBUTES command.
**pfield**

Is the field name of the common field from the parent segment, and is used to implement the Join relationship. It is required in dependent segment declarations for multi-segment structures.

**cfield**

Is the field name of the common field from the dependent segment, and is used to implement the Join relationship. It is required in dependent segment declarations for multi-segment structures.

**rtfield**

Is the field name for the Model 204 record type field that exists when a Model 204 file has several logical record types.

**rtvalue**

Is the value that identifies the Model 204 record type or a field name.

**ALL**

**nnnn/xxx**

**AUTO/xxx**

Indicates how OCCURS segments should be processed when all occurrences cannot fit into the buffer at once and a (FOC4883) IFMORE FAILED message results. ALL is the default value. These options are described in *Access Files for Model 204* on page 1418.

**Note:**

- For multi-segment structures, the order of the Access File segment declarations must correspond to the order in the Master File.
- Dummy segments used to link unrelated segments do not have corresponding segment declarations in the Access File.

**Reference:** **SEGNAME Attribute**

The SEGNAME value must be the first attribute in each Access File segment declaration. It must be identical to the SEGNAME value in the Master File.

**Reference:** **FILE and PASS Attributes**

The FILE and PASS attributes are required in each Access File segment declaration. They describe Model 204 file security information.
The value for the FILE attribute is the name of the Model 204 file or group that contains the logical record type. The value for the PASS attribute is either the read password associated with the Model 204 file or blank if the password does not exist. For both attributes, acceptable values are 1- to 8-character values.

Access Files can be encrypted to prevent access to this security information.

**Reference: CONNECTION Attribute**

The CONNECTION attribute may be used in the Access File on the segment level. The value of this attribute is the valid connection_name that was previously set by the SET CONNECTION_ATTRIBUTES command. If this attribute is used in the Access File, the file-level parameters must be omitted or they will be overwritten by the value from the SET command.

```plaintext
SEGNAME=RNG, CONNECTION=M204, FILE=RNG, $
   FIELD=FKEY, TYPE=KEY, ATTRIBUTE=FRV, $
   FIELD=FORC, TYPE=KEY, $
   FIELD=FORN, TYPE=KEY, $
   FIELD=FRNG, TYPE=RNG, $
```

**Syntax: How to Declare KEYFLD and IXFLD**

The KEYFLD and IXFLD attributes identify the common fields for parent/child relationships in a multi-segment Master File. These relationships are referred to as Embedded Joins, server views, or cross-references.

For each dependent segment, the KEYFLD and IXFLD attributes identify the field names of the common or shared field that implements the Embedded Join. The parent field supplies the value for cross-referencing; the dependent field contains the corresponding value. The adapter implements the relationship by matching values at run time.

The value for the KEYFLD attribute is a 1- to 66-character field or alias name from the parent segment. The value for the IXFLD attribute is a 1- to 66-character field or alias name from the dependent segment.

**Note:**

- Include the pair of attributes in Access File segment declarations for dependent segments. Do not specify them in the segment declaration for the root segment.

- Do not specify KEYFLD and IXFLD attributes for dependent segments of a virtual parent segment (PARENT=DUMMY).

A JOIN can be based on more than one field in the host and cross-referenced logical record types. If the Model 204 file uses multiple fields to establish a relationship or link between logical record types, you can specify concatenated fields in an Embedded Join (you can also specify multiple fields with the Dynamic JOIN command).
In a multi-field Embedded Join, the KEYFLD and IXFLD values consist of a list of the component fields separated by slashes (/). Additional Access File attributes are not required.

KEYFLD = field1/field2/....
IXFLD = cfield1/cfield2/....

where:

field1/...

Is a composite of up to 16 key fields from the parent segment. Slashes are required.
cfield1/...

Is a composite of up to 16 key fields in the dependent segment.

The adapter compares each field pair for comparable data formats prior to format conversion. It evaluates each field pair with the following rules:

- Any of the Model 204 key fields listed in Field Declarations can be used to create an Embedded Join.
- Parent and dependent fields must be real fields.
- All participating fields for either the parent or dependent file must reside in the same segment.
- KEYFLD and IXFLD attributes must specify the same number of fields. If the format of the parent field is longer than the format of the dependent field, its values are truncated. If the format of the parent field is shorter, its values are padded with zeros or blanks.
- The KEYFLD and IXFLD attributes can consist of a maximum of 16 concatenated fields in high to low significance order. You must specify the field order; the order determines how the values will be matched.
- Each pair of fields in the KEYFLD/IXFLD attribute must have comparable data formats. The formats of the parent fields must be compatible with the formats of the dependent fields as specified in the Model 204 file description.

To implement Joins, the Model 204 DBMS converts the alphanumeric server field formats to equivalent Model 204 field formats in order to perform the necessary search and match operations. When the Model 204 DBMS returns the answer set of matched values, it also converts the values back to alphanumeric formats.

Internally, each KEYFLD value is passed to the Model 204 DBMS in the IFFIND call to retrieve all matching records (segment instances) for the dependent segment.
Syntax: How to Declare RECTYPE and RECTVAL

The RECTYPE and RECTVAL attributes identify the Model 204 record type field and its corresponding value. A Model 204 record type field exists in a Model 204 file description when the file has more than one logical record type. If the Model 204 file consists of one logical record type, it may contain an optional record type field.

The value for the RECTYPE attribute is the 1- to 66-character field or alias name of the Model 204 record type field. The value for the RECTVAL attribute is the identifying value for the record type field; it can be up to 255 characters in length or a field name. The RECTVAL attribute is required whenever the RECTYPE attribute is used.

The RECTYPE and RECTVAL attributes are required in each Access File segment declaration (including the one for the root) if the Model 204 file contains record types.

Note: Do not use the name RECTYPE as a field name in the Master File.

ACCESS

How to:
Enter Field Declarations
Declare Field Attributes in an Access File

Reference:
Supporting Types of Key Fields

OCCURS segments are generally described only in the Master File and do not require corresponding segment declarations in the Access File. However, sometimes the number of occurrences retrieved for an OCCURS segment exceeds the Model 204 buffer capacity, causing an error condition. You can alter the processing of OCCURS segments by including a segment declaration in the Access File.

The Model 204 buffer is used to return data to IFAM2 applications. Buffer capacity is sometimes exceeded when both of the following conditions exist:

- A multiply occurring field repeats a large number of times (for example, 2000 occurrences).
- The total number of occurrences multiplied by the size of the OCCURS segment is greater than the size of the IFAMBS buffer (the IFAMBS size is specified as a parameter in the Model 204 startup procedure).

The size of the IFAMBS buffer is determined by a predefined formula:

\[
\text{IFAMBS} := (\text{LIBUFF} \times 7) + 284 + 32688
\]
When the buffer capacity is exceeded, the Model 204 DBMS sends the adapter the following message:

**IFMORE error M204.0903 - Results too long**

This causes the server message:

**(FOC4883) IFMORE FAILED**

If you encounter this condition, you can include a segment declaration in the Access File to alter the number of occurrences retrieved. The adapter incorporates your specification in its HLI call to the DBMS.

An OCCURS segment declaration in an Access File consists of two attributes, SEGNAME and ACCESS. The ACCESS attribute indicates the type of processing to be performed.

```
SEGNAME= name, ACCESS={ALL|nnnn[/xxx]|AUTO[/xxx]} ,$
```

where:

- **name**
  - Is the SEGNAME value for the OCCURS segment from the Master File.

- **ALL**
  - Indicates that the adapter will attempt to retrieve all occurrences of the OCCURS segment. ALL is the default value.

  **Note:** If the ACCESS attribute is omitted, the ALL setting is assumed.

- **nnnn**
  - Specify the largest number of occurrences that exists for the multiply occurring field. Based on the nnnn value, the adapter may manipulate the length of the QTBL buffer for the user session and then reset it to its original length.

- **AUTO**
  - Indicates that the adapter will retrieve up to 5000 occurrences. If there are more than 5000 occurrences, use nnnn instead of AUTO.

- **/xxx**
  - Instructs the adapter to issue multiple IFMORE calls, with each call retrieving xxx occurrences. This parameter is optional.

  Append to the nnnn or AUTO parameters to indicate that you want to control the number of records to be retrieved by each IFMORE call. If xxx is larger than the maximum allowed (based on the size of the buffers used by the Adapter for Model 204), you will receive the message:

  **(FOC4873) SPECIFIED NUMBER OF INSTANCES CANNOT FIT INTO BUFFER**
To correct the problem, decrease the xxx value and rerun the request.

**Note:**

- You can turn this feature on or off by defining the OCCURS segment in the Access File. OCCURS segments not described in the Access File undergo normal processing, which means that the ALL setting is assumed and all occurrences are retrieved at one time.
- If the SEGNAME attribute is specified in the Access File without the ACCESS attribute, ACCESS=ALL is assumed by default.
- Use this feature when the following message occurs:
  
  IFMORE error M204.0903 Results too long

**Syntax:** How to Enter Field Declarations

Field declarations in the Access File provide an alternate method for describing certain Model 204 field characteristics. Include a field declaration if the Model 204 field has a Model 204 key designation or if the Model 204 field name (the ALIAS attribute) exceeds 66 characters.

**Reference:** Supporting Types of Key Fields

The Model 204 DBMS supports a variety of key field types. The adapter supports the Model 204 key designations with comparable abbreviations called suffix operators. You describe these operators with the TYPE attribute in the Access File. The actual Model 204 key designation determines the proper suffix operator to apply.

The following chart lists Model 204 key designations and the corresponding suffix operators.

<table>
<thead>
<tr>
<th>Model 204 Key Designation</th>
<th>Master File Suffix Operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>KEY</td>
</tr>
<tr>
<td>Key, invisible</td>
<td>IVK</td>
</tr>
<tr>
<td>Ordered Character</td>
<td>ORA</td>
</tr>
<tr>
<td>Ordered Numeric</td>
<td>ORN</td>
</tr>
<tr>
<td>Numeric Range</td>
<td>RNG</td>
</tr>
<tr>
<td>Numeric Range, invisible</td>
<td>IVR</td>
</tr>
<tr>
<td>Ordered Character, invisible</td>
<td>IOA</td>
</tr>
<tr>
<td>Ordered Numeric, invisible</td>
<td>ION</td>
</tr>
</tbody>
</table>
**Note:** Master Files created in earlier server releases may contain field declarations with suffix operators for Model 204 key fields. While this earlier method is supported, the recommended method is to specify suffix operators in the Access File.

**Syntax:**

**How to Declare Field Attributes in an Access File**

```plaintext
FIELD=field [,ALIAS=m204field] [,TYPE=suffix] [,ATTRIBUTE=FRV],
[ACCDATA= {STR|NUM}] ,S
```

where:

- **m204field**
  - Is a Model 204 field name that exceeds 66 characters. 256 characters is the maximum amount.
  - **Note:** Omit the ALIAS attribute if the ALIAS attribute in the Master File already specifies the Model 204 field name.

- **suffix**
  - Is one of the suffix operators KEY, IVK, ORA, ORN, RNG, IVR, IOA, ION.

- **FRV**
  - This attribute value incorporates Model 204 FOR EACH VALUE processing on a BY field in a server COUNT request.

- **STR**
  - This attribute value will generate character string HLI selection tests for Model 204 fields that do not have a Model 204 key specification (Non-Ordered, Non-KEY, Non-Numeric Range).

- **NUM**
  - This attribute value will generate numeric HLI selection tests for Model 204 fields that do not have a Model 204 key specification (Non-Ordered, Non-KEY, Non-Numeric Range).

Two additional field attributes, ATTRIBUTE and ACCDATA are available:

- ATTRIBUTE will incorporate Model 204 FOR EACH VALUE processing on a BY field in a server COUNT request. The field defined with ATTRIBUTE=FRV must be a Model 204 Ordered field or a Model 204 KEY/FRV field.

- ACCDATA will instruct the adapter to generate either character string or numeric HLI selection tests for Model 204 fields that do not have a Model 204 key specification (Non-Ordered, Non-KEY, Non-Numeric Range).
Customizing the Model 204 Environment

In this section:

- Specifying a User Account and Password
- Specifying the Capacity of Adapter Buffers
- Controlling the Size of the FBTL Buffer
- Indicating Missing Data on Reports
- Locking Records to Ensure Accurate Data Reports
- Controlling Thread Management
- Displaying Adapter Defaults and Current Settings

How to:

Set Adapter Parameters

Each Master File for a Model 204 file must have a corresponding Access File. The name of the Access File must be the same as that of the Master File. In z/OS, the Access File PDS is allocated to ddname ACCESS in the server JCL. The Access File associates a segment in the Master File with the Model 204 logical record type it describes.

The Adapter for Model 204 provides several parameters for customizing the environment and optimizing performance. These parameters control or identify Model 204 account security, the size of all adapter buffers, the size of the Model 204 FTBL buffer, null values in reports, locked records, and thread management. Information Builders strongly recommends that you set these parameters when you configure the Adapter for Model 204 (see Connection Attributes for Model 204 on page 1388).

However, you can also use the legacy adapter SET commands to change parameters that govern the adapter's behavior. These parameters control or identify Model 204 account security, the size of all adapter buffers, the size of the Model 204 FTBL buffer, null values in reports, locked records, and thread management. To display current adapter parameter settings, issue the adapter M204IN SET ? query command. You can issue these commands from an RPC. They remain in effect for the duration of the server client task or until you change them.

Note: If the attribute CONNECTION is provided in the Access File, then values of parameters that were placed in the appropriate SET CONNECTION_ATTRIBUTES command will be used.
Syntax: **How to Set Adapter Parameters**

The syntax for adapter SET commands includes the ENGINE environment qualifier and the M204IN keyword.

```
ENGINE M204IN SET command value
```

where:

- **command**: Is an Adapter for Model 204 command.
- **value**: Is an acceptable value for the adapter command.

### Specifying a User Account and Password

**How to:**

**Specify a User Account and Password**

You can supply Model 204 user IDs, accounts, and passwords with the adapter M204IN SET M204ACCNT and M204PASS commands. Authorized accounts, user IDs, and passwords protect read access to Model 204 files or groups of files.

The M204IN SET M204ACCNT and M204PASS commands provide an alternative to supplying security information in encrypted Access Files. You can also use the M204IN SET M204ACCNT and M204PASS commands to override existing account and password values specified with the ACCOUNT and ACCOUNTPASS attributes in the Access File.

Syntax: **How to Specify a User Account and Password**

To specify an account, issue the following from the command level.

```
ENGINE M204IN SET M204ACCNT userid [account]
```

where:

- **userid**: Is the 1-10 character user ID by which you are known to Model 204.
- **account**: Is a string of 1-10 characters, to be used only if an account under which the user will log in to Model 204 must be supplied.

To specify a password for an account, issue the following from the command level.

```
ENGINE M204IN SET M204PASS password
```
where:

**password**

Is a 1- to 16-character password for the account.

**Note:** If you do not issue the SET commands or you leave the values blank, they default to the values of the ACCOUNT and ACCOUNTPASS attributes specified in the Access File.

### Specifying the Capacity of Adapter Buffers

**How to:**

Specify the Capacity of Adapter Buffers

You can set or change the maximum size of all adapter buffers with the M204IN SET MAXMBUFF command.

Before you issue the M204IN SET MAXMBUFF command, consider that the MAXMBUFF value:

- Should be greater than the larger of two Model 204 buffer settings, LIBUFF and LOBUFF. To identify which buffer is larger, check the parameters in the Model 204 start-up procedure or use the adapter Trace Facility (SET TRACEON=M204IN) to display the settings.

- Should be equal to the size of the largest segment in the Master File if the segment size is greater than the Model 204 LIBUFF and LOBUFF buffer settings. Having the maximum buffer size equal to that of the largest segment prevents S0C4 ABEND conditions.

**Syntax:**

**How to Specify the Capacity of Adapter Buffers**

```bash
ENGINE M204IN SET MAXMBUFF nnnn
```

where:

**nnnn**

Is the maximum size in bytes. For example, specify 4096 for a MAXMBUFF value of 4K. Unless you explicitly issue this command, it is not used and there is no default value.
Controlling the Size of the FBTL Buffer

How to: Control the Size of the FTBL Buffer

The M204IN SET FTBL command enables you to control the size of the Model 204 FTBL buffer. The LFTBL parameter, specified in the Model 204 start-up procedure, governs the size of the FTBL buffer. You can change it for the current client session only. Issue this command when a Model 204 message indicates that the LFTBL value is too small.

Syntax: How to Control the Size of the FTBL Buffer

ENGINE M204IN SET FTBL nnnn

where:

nnnn

Is the FTBL size in bytes. For example, specify 4096 for an FTBL value of 4K.

You should set FTBL to a value larger than the previously defined Model 204 LFTBL value.  

Note: The FTBL value you set applies for the current user session only; it is reset when the session is ended.

Indicating Missing Data on Reports

How to: Indicate Missing Data on Reports

With the adapter M204IN SET MISSING command, you can control the display of Model 204 null data on reports. Null data is translated into the server missing data display value. The default NODATA display value is the period (.). When the adapter MISSING attribute is set to ON, the edit specification for all IFGET calls includes an (L) format code. If Model 204 returns a zero in the first byte, the adapter considers that field to be missing.

Note: IFFIND calls contain IS PRESENT or IS NOT PRESENT criteria only when the request includes a server IF or WHERE MISSING selection test.

Syntax: How to Indicate Missing Data on Reports

ENGINE M204IN SET MISSING {ON|OFF}
where:

**ON**

Uses the NODATA value to display Model 204 null data.

**OFF**

Null values are not represented on reports. OFF is the default value.

**Note:**

- The default setting can affect the results of server DML SUM or COUNT aggregate operations. Null values may be counted or averaged in as existing values.
- You must issue the M204IN SET MISSING ON command in order to specify screening conditions (IF or WHERE MISSING tests) for null values.

**Locking Records to Ensure Accurate Data Reports**

When retrieving records, the Model 204 DBMS usually holds locks on the appropriate records to ensure accurate data for reports. The locks prevent other users from updating the target records while Model 204 constructs answer sets. The adapter generates standard IFFIND calls that lock the found set in SHR mode.

For certain circumstances, you can issue the adapter SET READWOL (read without locks) command to instruct the adapter to issue an IFFWOL (find without locks) HLI call. Use the following syntax to turn the setting ON:

```
ENGINE M204IN SET READWOL ON
```

For information about the design and performance considerations involved in deciding when to use the Model 204 IFFWOL command instead of the IFFIND command, consult the *Model 204 Host Language Adapter Programming Guide*.

**Controlling Thread Management**

| **How to:** |
| Change the Mode of Thread Management |

The adapter M204IN SET SINGLETThread command enables you to control Model 204 thread management during record retrieval. A thread is a communications path or link between the adapter and the Model 204 DBMS. Adapter requests (generated HLI calls) are transmitted using threads. Threads are de-allocated after each adapter request is processed.

There are two types (or modes) of thread management:

- **Multiple.** The adapter creates as many threads as it needs whenever they are needed to access files.
Single. The adapter creates one thread for all file access. This restricts processing to one request.

**Syntax:**

How to Change the Mode of Thread Management

To change the mode, issue the following from the command level

```sql
ENGINE M204IN SET SINGLETHREAD {ON|OFF}
```

where:

**ON**

Forces the adapter to use a single thread for all file access.

**OFF**

Allows the adapter to use multiple threads. OFF is the default value.

For example, if a request joins 10 files and the SINGLETHREAD setting is ON, only one thread is used to access all of the files. If the setting is OFF, up to 10 threads may be used. For performance reasons, the OFF setting is recommended.

**Displaying Adapter Defaults and Current Settings**

The adapter M204IN SET ? query command displays adapter defaults and current settings. Issue the following:

```sql
ENGINE M204IN SET ?
```

**Using Customized Security Exits**

How to:

Specify a Security Exit

Reference:

Security Exit Processing

Your database administrator can provide Model 204 logon and account information with security exits written in COBOL or Assembler. The adapter supports this method of supplying security information through exit parameters.

The security exit is site specific and must be named M204EXT. The M204EXT program is executed only when the ACCOUNT name and PASSWORD have not been previously defined to the adapter either in the Access File, with a Dialogue Manager &variable, or by issuing the M204IN SET commands.
**Syntax:**  How to Specify a Security Exit

The adapter calls the M204EXT exit with the following syntax:

```
CALL M204EXT(USR, ACCNT, ACCNTP)
```

where:

**USR**

Is the 8 character TSO or MSO logon userid that is passed to the security exit.

**ACCNT**

Is the 16 character Model 204 account (userid) that is returned from the exit.

**ACCNTP**

Is the associated 16 character account password that is returned from the exit.

**Reference:**  Security Exit Processing

When a user issues a report request to access Model 204 data, the adapter calls the M204EXT exit using standard IBM calling conventions and passes the three parameters to the exit. Based on the supplied userid (USR), the exit returns the account and password values to the adapter, which uses the returned values to generate the IFSTRTN call. (The IFSTRTN call initiates an internal logon to the Model 204 DBMS before the user request for services is executed.) After generating the IFSTRTN call, the adapter erases the values from memory.

To use the security exit, the database administrator must:

1. Write the security exit in COBOL or Assembler. The program name must be M204EXT.

   A sample Assembler M204EXT security exit program is provided in the 'FOCM204.DATAM204EXT)' data set. The sample can be modified according to your site standards.

2. Link edit the object module into a load library with AMODE(31). For example:

   ```
   //LINK    EXEC PGM=IEWL,
   //         PARM='LET,NCAL,SIZE=(1024),LIST'
   //OBJLIB   DD   DSN=objlib.LOAD,DISP=SHR
   //SYSLMOD DD   DSN=loadlib.LOAD,DISP=SHR
   //SYSLIN  DD   UNIT=SYSDA,SPACE=(CYL,(10,1))
   //SYSUT1   DD   UNIT=SYSDA,SPACE=(CYL,(10,1))
   //SYSPRINT DD   SYSOUT=*
   //SYSLIN  DD   *
   INCLUDE OBJLIB(M204EXT)
   MODE   RMODE(31),AMODE(31)
   ENTRY M204EXT
   NAME M204EXT(R)
   /*
   ```
where:

**objlib.LOAD**

Is the name of the partitioned data set (PDS) that contains the M204EXT object code.

**loadlib.LOAD**

Is the load library that is to contain the M204EXT load module.

3. Concatenate the load library (allocated to ddname SYSLMOD in Step 2) to ddname USERLIB in the TSO CLIST that you use to invoke the server, or to ddname STEPLIB in your TSO logon CLIST.

   For MSO, either link the M204EXT load module into the 'prefix.FOCLIB.LOAD' data set, or allocate it to ddname STEPLIB.

### Adapter Tracing for Model 204

<table>
<thead>
<tr>
<th>How to:</th>
<th>Activate Adapter Tracing</th>
</tr>
</thead>
</table>

The Adapter for Model 204 Tracing Facility is activated from the Web Console main page.

**Procedure: How to Activate Adapter Tracing**

1. From the Web Console menu bar, select *Workspace*, then *Diagnostics* and *Traces*. The Trace pane opens.

2. Click *Enable Traces*.

   The default traces include the Adapter for Model 204 tracing information.
Using the Adapter for MQSeries

The Adapter for MQSeries allows applications to access MQSeries data sources. The adapter converts application requests into native MQSeries statements and returns optimized answer sets to the requesting application.

Topics:
- Preparing the MQSeries Environment
- Configuring the Adapter for MQSeries
- Managing MQSeries Metadata
- Customizing the MQSeries Environment
Preparing the MQSeries Environment

The MQSeries adapter requires the installation and configuration of the MQSeries client to allow you to connect to a local or remote MQSeries database server.

Configuring the Adapter for MQSeries

In this section:
Issuing a FILEDEF Command

How to:
Configure the Adapter

You can configure the Adapter for MQSeries from the Web Console or the Data Management Console.

If you plan to create a synonym manually, you must also first issue a FILEDEF command.

Procedure: How to Configure the Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   or
   From the Data Management Console, expand the Adapters folder.
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Note: The MQSeries adapter is under the Sequential and Indexed group folder. No input parameters are required.
Issuing a FILEDEF Command

If you plan to create a synonym manually, you must first issue a FILEDEF command. Because a queue in MQSeries can be viewed as a sequential file, the server uses the logical layer of a flat file interface. In order to distinguish between sequential file storage types and MQSeries storage types, you must issue the FILEDEF command prior to any read/write request against MQSeries. FILEDEF is used to provide definitions for the queue manager, the queue name, and the optional message ID to the MQI layer.

Syntax: How to Issue the FILEDEF Command

FILEDEF master QMAN queuemgr QUEUE queue name [MSGID msg_id]

where:

master
Is the Master File name used to provide the dynamic definitions of the queue manager, the queue, and the optional message ID.

queuemgr
Is the name of the queue manager.

queue name
Is the name of the queue.

msg_id
Is the optional parameter used when producing messages in a queue that are defined outside of the program assigned message ID.
Managing MQSeries Metadata

**Managing MQSeries Metadata**

*In this section:*
- Creating Synonyms
- Retrieving Foreign Messages From the Queue
- Data Type Support

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the MQSeries data types.

For the Adapter for MQSeries to access MQSeries files, you must describe each file you use in a Master and Access File. The logical description of an MQSeries file is stored in a Master File, which describes the field layout.

**Creating Synonyms**

**How to:**

Create a Synonym

**Example:**

Creating a Synonym

**Reference:**

Synonym Creation Parameters for MQSeries

Managing Synonyms

Synonyms define unique names (or aliases) for each MQSeries data structure that is accessible from a server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File.

**Procedure:  How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.
1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym
   creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**
- You can also create a synonym from the Adapters page by right-clicking a configured
  adapter connection and selecting Create Synonym.
- When creating a synonym, if you choose the Validate check box (where available), the
  server adjusts special characters and checks for reserved words. For more information,
  see Validation for Special Characters and Reserved Words on page 2821.

**Reference:** Synonym Creation Parameters for MQSeries

The following list describes the parameters for which you will need to supply values, and
related tasks you will need to complete in order to create a synonym for the adapter. These
options may appear on multiple panes. To advance from pane to pane, click the buttons
provided, ending with the Create Synonym button, which generates the synonym based on
your entries.

**QMGR**
In the QMGR input field, enter the name of the queue manager on the machine where
the server resides.

**QUEUE**
In the QUEUE input field, enter the message queue.

**Application**
Select an application directory. The default value is baseapp.
Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

Select messages

To select all messages in the queue, click the check box to the left of the Default Synonym Name column heading.

To select specific messages in the queue, click the corresponding check boxes.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Example:** Creating a Synonym

To generate the following synonym for the variable mqpro from the Web Console or the Data Management Console:

1. In the QMGR input field, enter edarisc64 as the name of the queue manager on the machine where the server resides.
2. In the QUEUE input field, enter MQHOLD1 as the message queue.
3. Click Select Operations.
4. On the second Create Synonym pane, choose 41423 from the list of messages in the queue, and click Create Synonym.
   
   The synonym is created and added under the specified application directory (baseapp is the default).

   A status window displays the message: All Synonyms Created Successfully
5. From the message window, click Applications on the menu bar.
6. Open the baseapp application folder in the navigation pane and click the synonym 41423.
7. Choose *Edit as Text* from the menu to view the generated Master File. Your entries are reflected in the DATASET field.

**Generated Master File**

FILE =MQPRO,
SUFFIX =MQS,
DATASET ="edarisc64"."MQHOLD1",
4142300000000000000000000000000000000000000000000, $
SEGNAME =MQPRO ,
SEGTYPE =S0
FIELDNAME=DIVISION4       ,E01         ,I11      ,I04     ,$
FIELDNAME=DIVISION_NA4    ,E02         ,A25      ,A28     ,
MISSING =ON, $
FIELDNAME=DIVISION_HE4    ,E03         ,I11      ,I04     ,
MISSING =ON, $
$FIELD   =MSGID,
$ ALIAS  =414230000000000000000000000000000000000000000000,
USAGE    =A48,A48,$
$FIELD   =CORID,
$ ALIAS  =4942495F434F525F49443200000000000000000000000000000000,
USAGE    =A48,A48,$
$FIELD   =TIMEOUT,
ALIAS    =0,
USAGE    =I4,I4,$

**Note:** An Access File is not generated when you create a synonym from an MQSeries queue.

**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td><strong>Option</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Edit Access File as Text</strong></td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td><strong>Sample Data</strong></td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td><strong>Data Profiling</strong></td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td><strong>Refresh Synonym (if applicable)</strong></td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td><strong>Data Management</strong></td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>

### Retrieving Foreign Messages From the Queue

**Example:**

Retrieving Foreign Messages From the Queue

You may receive the following types of messages:

- **Server Family Messages.** Messages created by the Adapter for MQSeries. These messages are stored as logical sets, metadata, and data. This implementation allows the server to store results of queries on the sending end, recreate metadata on the receiving end, and retrieve the data as it would from any relational data source. Access to any DBMS requires an active connection, which is not always available. One example of an implementation would be an asynchronous DBMS access.

- **Foreign Messages.** Messages produced by non-server software. The adapter can retrieve any message, but the user must first create metadata.

**Example:**

Retrieving Foreign Messages From the Queue

The Master File must be created manually. For example:

```
FILE=MQS1, SUFFIX=MQS,$
DATASET=edarisc3.MQHOLD1.41423, $
SENGNAME=ROOT, SEGTYPE=S0,$
FIELD=MESSAGE, ALIAS=AA, USAGE=A720, A720 ,$
     GROUP=SPECIALS, ALIAS=, USAGE=A100, A100 ,$
     FIELD=MSGID ALIAS=, USAGE=A48, A48 ,$
     FIELD=CORID, ALIAS=, USAGE=A48, A48 ,$
     FIELD=TIMEOUT, ALIAS=0, USAGE=I4, I4 ,$
```
Data Type Support

Data types in foreign messages are generated by application programs writing to the queues. If a COBOL copy book describing data layout exists, the metadata type could be generated by COBOL FD Translator.

The following chart provides information about the default mapping of MQSeries data types to server data types:

<table>
<thead>
<tr>
<th>COBOL Format</th>
<th>Data Type</th>
<th>ACTUAL</th>
<th>USAGE</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>PICTURE S9(n) V9(m) COMP-3</td>
<td>P(n+m+2/2)</td>
<td>Pn+m+2.m</td>
<td></td>
</tr>
</tbody>
</table>
The format conversions are subject to the following limitations:

- Alphanumeric fields are limited to 256 characters. Elementary fields that exceed 256 characters are truncated to 256 characters and have filler fields inserted to provide for the total length. Group fields that exceed 256 characters are commented.

- Unsigned zoned fields that exclude a decimal point are described with a USAGE of packed (P) or alphanumeric (A), depending on the value entered for the Zoned Numeric Field Usage option on the Translator menu.

- COMP-4 binary fields are described the same as COMP fields.

- Binary fields that exceed 9 digits in the picture clause are described with ACTUAL format A8 and USAGE format A8.

The maximum length of the packed USAGE format depends on the software release that uses the generated Master File. For releases that support long packed fields (16 or more digits), the maximum ACTUAL length is 16 bytes and the maximum USAGE length is 31 digits (or 32 characters including a decimal point and sign). For earlier releases, the maximum ACTUAL length is 8 bytes and the maximum USAGE length is 15 total digits, including decimal and sign. The number of decimal places is limited to one fewer than the total USAGE length. In general, the USAGE length of packed fields is calculated as the sum of the digits to the left of the decimal (n), the number of decimal positions (m), one for the leading minus sign if present (S), and one for the decimal (V) if present.

The ACTUAL and USAGE formats for GROUP fields are always alphanumeric (A). The ACTUAL length is the sum of the ACTUAL lengths of its components. The USAGE length is the sum of the following:

- The USAGE lengths of all the alphanumeric (A) components.
- 16 for each long packed (P) component.
- 8 for each short packed (P) and double precision (D) component.
- 4 for each integer (I) and floating point (F) component.

**Customizing the MQSeries Environment**

**In this section:**

Specifying Read Mode

The Adapter for MQSeries provides a parameter that enables you to customize how data is read and subsequently handled.
Specifying Read Mode

How to: Set Read Mode for MQSeries Data

By default, the Adapter for MQSeries deletes data from a queue after reading it. The alternative is to browse the data without deleting it.

Syntax: How to Set Read Mode for MQSeries Data

Tip: You can change this setting manually or from the Web Console by clicking Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the right-click menu. The Change Settings pane opens.

To specify a Read Mode, choose the one of the following values

ENGINE MQS SET MQMREADMODE {R|B}

where:

R

Reads data and deletes it from a queue. This is the default setting.

B

Browses data without deleting it from a queue.
The Adapter for Digital Standard Mumps allows applications to access Mumps data sources. The adapter converts application requests into native Mumps statements and returns optimized answer sets to the requesting application.

**Topics:**
- Preparing the Mumps Environment
- Configuring the Adapter for Digital Standard Mumps
- Managing Mumps Metadata
- Including Records in a Mumps Data Source
Preparing the Mumps Environment

To prepare the Mumps environment on OpenVMS, the system administrator must set the following logicals:

```plaintext
DSM$DEFAULT_DSMAXP028 = /SOURCE_BUFFER_SIZE = 65535/SYMBOL_TABLE_SIZE=300000
DSM$ENVIRONMENT = DSMAXP028
DSM$ID_DSMAXP028 = 00001
```

Configuring the Adapter for Digital Standard Mumps

In this section:
Declaring Connection Attributes

Configuring the adapter consists of specifying connection information for each of the connections you want to establish.

Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Example:
Declaring Connection Attributes

Reference:
Connection Attributes for Digital Standard Mumps

In order to connect to Mumps, the adapter requires connection information. You supply this information using the SET CONNECTION_Attributes command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).
**Procedure:** How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**.
   
   or
   
   From the Data Management Console, expand the **Adapters** folder.
   
   The Adapters folder opens.

2. Expand the **Available** folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select **Configure**.
   
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click **Configure**. The configured adapter is added to the Adapters list in the navigation pane.

**Reference:** Connection Attributes for Digital Standard Mumps

The MUMPS adapter is under the **DBMS** group folder.

This chart describes the connection attributes for which you can supply values. To complete the attribute declaration, click the **Configure** button.

**Volume Name**

The volume set name where the global data structure exists.

Note that this value determines the list of UCIs that are displayed when you create a synonym.

**Recovery Mode**

Indicates whether recovery mode is turned ON or OFF for the specified volume.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.
If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:**

**How to Declare Connection Attributes Manually**

ENGINE DSM SET CONNECTION_ATTRIBUTES volume recovery_mode

where:

**DSM**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**volume**

Is the volume set name where the global data structure exists.

**recovery_mode**

Indicates whether recovery mode is turned ON or OFF for the specified volume set name.

**Example:**

**Declaring Connection Attributes**

The following illustrations configure the adapter using different volume and recovery specifications:

ENGINE DSM SET CONNECTION_ATTRIBUTES ;RAQ:RECOVERY=ON

ENGINE DSM SET CONNECTION_ATTRIBUTES ;qaq:RECOVERY=OFF

**Managing Mumps Metadata**

**In this section:**

Creating Synonyms

Data Type Support

Handling Dates

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Mumps data types.
Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Creating a Synonym
Master File Clinic With Redefined Data

**Reference:**
Synonym Creation Parameters for Digital Standard Mumps
Managing Synonyms
Access File Keywords

Synonyms define unique names (or aliases) for each Mumps table or view that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   
   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   
   The *Select adapter to configure* or *Select connection to create synonym* pane opens.

3. Click a connection for the configured adapter.
   
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*. 
The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:**  **Synonym Creation Parameters for Digital Standard Mumps**

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

**Select UCIs**

If you wish to filter UCIs (User Class Identifiers), click the Filter UCIs check box and enter a UCI name, then click *Next*.

To select all UCIs, simply click *Next*.

Note that the list of UCIs displayed depends on the volume that was specified when the adapter was configured.

**Select tables**

Choose the UCI that contains the tables (globals) for which you wish to create synonyms, then click *Select Tables*.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.
**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**Select globals**

To select all globals in the list, select the check box to the left of the *Default Synonym Name* column heading.

To select specific globals, select the corresponding check boxes.

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Mark for Global Scan**

The Mark for Global Scan check box is activated for all selected globals.

- Click the check box if you wish to create a synonym that is ready for reporting, based on default subscript names.

- Do not click the check box if you wish to create a synonym template that you can modify manually by entering actual field names before you use it for reporting. The template contains 25 segments.

  **Tip:** You can modify the synonym manually from the navigation pane in the Web Console or the Data Management Console. Right-click the synonym and choose either *Edit as Text* to open a text editor or *Edit/Open* to open a graphical viewing/editing tool.

**Example: Creating a Synonym**

To generate a synonym for the global Civic, enter the following information on the Create Synonym panes of the Web Console or the Data Management Console:

1. On the first Create Synonym pane, click the *Next* button since filtering UCIs is not required for this example.

   Note that the list of UCIs displayed depends on the volume you specified when you configured the adapter. In this example, the volume is RAB.

2. On the second Create Synonym pane, choose *EDA* as the UCI that contains the tables (globals) for which you wish to create synonyms, then click *Select Tables*.

3. On the third pane, select the global *CLINIC* from the displayed list.
4. Click Create Synonym. The synonym is created and added under the specified application directory (baseapp is the default).

A status window displays the message: All Synonyms Created Successfully

5. From the message window, click Applications on the menu bar.

6. Open the baseapp application folder in the navigation pane and click the synonym clinic.

7. Choose Edit as Text from the menu to view (and edit) the generated Master File.

**Generated Clinic Master File**

```plaintext
FILE=CLINIC, SUFFIX=DSM, $
SEGMENT=GLOBAL, SETYPE=U, $
   FIELD=DUMMY, ALIAS=SUBSCRIPT, USAGE=A1, ACTUAL=A1, $
   FIELD=GLOBAL_VALUE, ALIAS=GLOBAL_VALUE, USAGE=A512, ACTUAL=A512, $
SEGMENT=SUB1, SETYPE=S0, $
   FIELD=SUB1, ALIAS=SUBSCRIPT, USAGE=A245, ACTUAL=A245, $
SEGMENT=SUB2, SETYPE=S0, $
   FIELD=SUB2, ALIAS=SUBSCRIPT, USAGE=A245, ACTUAL=A245, $
SEGMENT=SUB3, SETYPE=S0, $
   FIELD=SUB3, ALIAS=SUBSCRIPT, USAGE=A245, ACTUAL=A245, $
   FIELD=VAL3, ALIAS=VAL3, USAGE=A512, ACTUAL=A512,
```

Note that, unlike other databases, Mumps does not provide column names. Therefore, the API does not return column names. All columns are assigned names prefixed with SUB and numbered sequentially (SUB1, SUB2,..., SUBn). However, if you wish you can manually change the field names generated in the synonym to make them more descriptive. Data value fields are placed in the segment associated with the subscript. Data values might contain a sequence of variable length fields delimited by special characters. These delimiting characters are described in the Access File and are associated with subscript segments.

8. Close the Master File in the text editor and click the synonym clinic again. This time choose Edit Access File as Text from the menu.

**Generated Clinic Access File**

```plaintext
UCI=EDA, VOLUMESET=RAB, GLOBAL=CLINIC, CARDINALITY=6, WRITE=NO, $
SEGNAME=GLOBAL, DELIMITER=,$
SEGNAME=SUB3, DELIMITER=,$
```
**Example:**  **Master File Clinic With Redefined Data**

To facilitate reporting, you can manually redefine data in the Master File, as illustrated in an edited version of the Master File synonym Clinic, where the field VAL3 has been redefined. To compare the edited version with the original, see *Creating a Synonym* on page 1455.

```
FILE=CLINIC, SUFFIX=DSM, $
SEGMENT=GLOBAL, SEGTYPE=U, $
   FIELD=DUMMY, ALIAS=SUBSCRIPT, USAGE=A1, ACTUAL=A1, $
   FIELD=GLOBAL_VALUE, ALIAS=GLOBAL_VALUE, USAGE=A512, ACTUAL=A512, $
SEGMENT=SUB1, SEGTYPE=S0, $
   FIELD=SUB1, ALIAS=SUBSCRIPT, USAGE=A245, ACTUAL=A245, $
SEGMENT=SUB2, SEGTYPE=S0, $
   FIELD=SUB2, ALIAS=SUBSCRIPT, USAGE=A245, ACTUAL=A245, $
SEGMENT=SUB3, SEGTYPE=S0, $
   FIELD=SUB3, ALIAS=SUBSCRIPT, USAGE=A245, ACTUAL=A245, $
   FIELD=VAL3, ALIAS=VAL3, USAGE=A512, ACTUAL=A512, $
SEGMENT=SUB3RED, SEGTYPE=S0, PARENT=SUB3, POSITION=VAL3, $
   FIELD=VAL3A, ALIAS=VAL3A, USAGE=A4, ACTUAL=A4, $
   FIELD=VAL3B, ALIAS=VAL3B, USAGE=A4, ACTUAL=A4, $
   FIELD=VAL3C, ALIAS=VAL3C, USAGE=A9, ACTUAL=A9, $
   FIELD=VAL3D, ALIAS=VAL3B, USAGE=P6.2, ACTUAL=A6, $
```

**Tip:** To edit the Master File, click the synonym and choose either *Edit as Text* to open a text editor or *Open* to open a graphical viewing/editing tool.

**Reference:**  **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>

<td>Specifies whether write operations are allowed against the table.</td>
</tr>
</tbody>
</table>

**Data Type Support**

All data in DSM Mumps is represented as alphanumeric. The format of the data can be changed manually in the USAGE attribute of the Master File. For example, see the VAL3D field in the previous example.

**Handling Dates**

Mumps dates are represented as the number of days that have elapsed since Jan 1841, or its equivalent, Dec 31, 1840. (Mumps does not use Julian date format.)

There are two ways to convert Mumps dates:
Using a procedure (for example, DATE.fex) to convert the date, as illustrated in the following sample code:

```
-SET &BASEOFF = 'DEC 31 1900' - 'DEC 31 1840'; <= 21914 is the number of elapsed days between the noted dates; it is stored in the variable &BASEOFF
```

```
DEFINE FILE CAR
BASEDATE/YYMD = 0 - &BASEOFF;
XDATE/YYMD = 59823 - &BASEOFF; <= 59823 is the Mumps date for october 15, 2004
END
TABLE FILE CAR
PRINT COUNTRY BASEDATE XDATE
END
```

Redefining a field in the Master File to converts the date, as illustrated in the following sample code:

```
Field=birthday Usage=A5 , Actual=A5,$
Field=birthday Usage=I5, Actual=A5,$ <= redefine the field using a DEFINE command
```

```
DEFINE birth/YYMD = birthday - 21914
```

### Including Records in a Mumps Data Source

**Example:**

**Modifying a Mumps Data Source**

You can include records in a Mumps data source using a technique in which fields from all the segments are active before the INCLUDE command is processed for some non-last segment called X. The adapter receives the sequence of INCLUDE commands for all the segments, starting with X and proceeding to the last segment. However, all of the INCLUDE commands except the last one are ignored. As the result, only the terminal node is written to the Global Variable even if non-terminal nodes with the corresponding keys do not exist.

Note that this approach differs from the "SQL style" in which a MODIFY request is structured by segments. Only fields from the processed segment are active in each segment related to the MODIFY case. As a result, all non-existing key fields for processed segments are inserted.

The technique is designed to support DataMigrator MODIFY requests against a Mumps data source.
**Example:** Modifying a Mumps Data Source

The following MODIFY request was generated by DataMigrator for transferring data from the file CARFLAT to the file MYCAR.

```
MODIFY FILE mycar
   FIXFORM FROM CARFLAT ALIAS PROPAGATE
   GOTO MATCHIT1

CASE MATCHIT1
   COMPUTE
   DUMMY/A1='';
   SUB1/A7=SUBSTR(7, COUNTRY, 1, 7, 7, 'A7');
   SUB2/A7=SUBSTR(7, CAR, 1, 7, 7, 'A7');
   SUB3/A7=SUBSTR(7, BODYTYPE, 1, 7, 7, 'A7');
   SUB4/A7=EDIT(SEATS);
   MATCH DUMMY
      ON NOMATCH INCLUDE
      ON MATCH CONTINUE
   MATCH SUB1
      ON NOMATCH INCLUDE
      ON MATCH CONTINUE
   MATCH SUB2
      ON NOMATCH INCLUDE
      ON MATCH CONTINUE
   MATCH SUB3
      ON NOMATCH INCLUDE
      ON MATCH CONTINUE
   MATCH SUB4
      ON MATCH REJECT
      ON NOMATCH INCLUDE
   GOTO TOP
ENDCASE

CASE AT START
   START &STARTAT
   STOP &STOPAT
   STOP DBMSERRORS &DBMSERROR
   LOG DBMSERR MSG OFF
   LOG DUPL MSG OFF
   LOG INVALID MSG OFF
   LOG NOMATCH MSG OFF
   LOG FORMAT MSG OFF
   LOG ACCEPT MSG OFF
   LOG TRANS MSG OFF
   CHECK 1000
ENDCASE
DATA ON CARFLAT
END
```
Using the Adapter for MySQL

The Adapter for MySQL allows applications to access MySQL data sources. The adapter converts application requests into native MySQL statements and returns optimized answer sets to the requesting application.

Topics:
- Preparing the MySQL Environment
- Configuring the Adapter for MySQL
- Managing MySQL Metadata
- Customizing the Adapter for the MySQL Environment
- Optimization Settings
Preparing the MySQL Environment

In this section:
MySQL and Unicode

How to:
Prepare the MySQL Environment on Windows
Prepare the MySQL Environment on UNIX

The Adapter for MySQL requires the MySQL Connector/J JDBC driver. For Release 5.x, Version 5.0.4 or higher is required. For Release 3.x, Version 3.1.14 or higher is required.

In order to report against Unicode data in MySQL, you must enable Unicode support in the reporting server. For more information, see MySQL and Unicode on page 1466.

Procedure: How to Prepare the MySQL Environment on Windows

1. Specify the location of the MySQL Connector/JDBC driver files in the CLASSPATH environment variable. You must specify the full location and name of the jar file. For example, if the jar file is located in C:\Program Files\MySQL\JDBC Driver, then specify:

   CLASSPATH= C:\Program Files\MySQL\JDBC Driver\mysql-connector-java-5.1.17-bin.jar

2. Specify the location of the Javarun time environment or development kit in the JAVA_HOME or JDK_HOME environment variable. Either is acceptable.

   You must specify the location where the run time environment is installed. You should see a sub-directory bin in that directory. For example, if you have the run time environment in C:\Program Files\java\jre6 then specify:

   JAVA_HOME=C:\Program Files\java\jre6

   Alternately, if you have the full development kit installed in C:\Program Files\java\jdk1.6.0_17, then specify:

   JDK_HOME= C:\Program Files\java\jdk1.6.0_17

3. Start (or restart) the server.

   Note: You also need to restart the server if the driver has changed.

Procedure: How to Prepare the MySQL Environment on UNIX

Specify the location of several files:
1. Specify the location of the MySQL Connector/JDBC driver files in the $CLASSPATH environment variable.
   
   For example, if the files are located in /usr/driver_files, you would issue the following statements:
   
   ```bash
   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH
   
   To ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.
   
   Alternatively, you could use the Web Console to specify the location:
   
   a. From the Workspace menu, select Configuration/Monitor.
   b. Expand the Java Services folder, right-click DEFAULT, and select Properties.
      
      The Java Services Configuration pane opens.
   c. Select the Class path section.
   d. Specify the full path to the MySQL Connector/J jar file in the IBI_CLASSPATH field.
   e. Click Save and Restart Java Services.
   
2. Specify the location of the Java Development Kit’s installation directory in the $JDK_HOME environment variable.
   
   For example, if you want to set the location of the Java Development Kit to /usr/java, you would issue the following statements:
   
   ```bash
   PATH=/usr/java
   export PATH
   
   3. Specify the location of the Java Virtual Machine’s installation directory in the $LD_LIBRARY_PATH environment variable.
   
   For example, if you want to set the location of the JVM to /usr/j2sdk1.4.2_01/jre/lib/i386/server, you would issue the following statements:
   
   ```bash
   LD_LIBRARY_PATH=/usr/j2sdk1.4.2_01/jre/lib/i386/server
   export LD_LIBRARY_PATH
   
   Note that if the server is running with security on, the LD_LIBRARY_PATH variable is ignored. In this case, you must use IBI_LIBPATH.
   
   4. Start (or restart) the server.
   
   Note: You also need to restart the server if the driver has changed.
MySQL and Unicode

The Adapter for MySQL is implemented using JDBC. This implementation supports Unicode data stored in character fields with the CHARACTER SET set to UTF-8.

You must set the LANG environment variable in the edastart file or in a separate shell file before you start the server. For example, for American English you would export the following variable:

```bash
export LANG=EN_US.UTF-8
```

For details, see Unicode Support in the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual.

Configuring the Adapter for MySQL

In this section:
- Declaring Connection Attributes
- Authenticating a User
- Overriding the Default Connection
- Controlling Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

How to:
- Declare Connection Attributes
- Declare Connection Attributes Manually

Example:
- Declaring Connection Attributes

Reference:
- Connection Attributes for MySQL

The SET CONNECTION_ATTRIBUTES command allows you to declare a connection to one MySQL database server and to supply authentication attributes necessary to connect to the server.
You can declare connections to more than one MySQL database server by issuing multiple
SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the
first query referencing that connection is issued (see Overriding the Default Connection
on page 1471). You can include SET CONNECTION_ATTRIBUTES commands in an RPC or a server
profile. The profile can be encrypted.

If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The first SET CONNECTION_ATTRIBUTES command sets the default MySQL database
  server to be used.
- If more than one SET CONNECTION_ATTRIBUTES command declares the same MySQL
database server, the authentication information is taken from the last SET
CONNECTION_ATTRIBUTES command.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   
   or
   
   From the Data Management Console, expand the Adapters folder.
   
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is
described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection
attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation
pane.
Reference: Connection Attributes for MySQL

The MySQL adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**URL**

Enter the location URL for the MySQL data source. The basic syntax is

```
jdbc:mysql://host/database
```

where:

- **host**
  - Is the computer name or IP address on which the MySQL database is located.

- **database**
  - Is the name of the database.

These are two examples:

```
jdbc:mysql://localhost/qatst
jdbc:mysql://edaaix52/qatst
```

Beginning with MySQL Release 4.1, you can reference additional MySQL connection properties in the URL. If you wish to do so, follow these guidelines: in the URL the first property must be preceded by the ? character, and the second and subsequent properties referenced in the URL must be preceded by the & character followed immediately by an | character, as illustrated in the following example.

Suppose that you wish to add the following connection properties:

- `sessionVariables=sql_mode=PIPES_AS_CONCAT`
- `zeroDateTimeBehavior=convertToNull`

Enter the URL as follows:

```
jdbc:mysql://host/database?sessionVariables=sql_mode=PIPES_AS_CONCAT|zeroDateTimeBehavior=convertToNull
```

**Note:** The URL must be entered as a single line, without a space after the | character.

**Driver name**

Name of the Microsoft JDBC driver: `com.mysql.jdbc.Driver`
Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:** How to Declare Connection Attributes Manually

For explicit authentication:

```
ENGINE MYSQL SET CONNECTION_ATTRIBUTES [connection]/userid,password
```

For password passthru authentication:

```
ENGINE MYSQL SET CONNECTION_ATTRIBUTES connection/
```

where:

- **MYSQL**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  
  The name of the connection. You can give any name to the connection that you want.

- **userid**
  
  Is the primary authorization ID by which you are known to MySQL.
Is the password associated with the primary authorization ID.

**Example: Declaring Connection Attributes**

The following SET CONNECTION_ATTRIBUTES command connects to the MySQL database server named TEST with an explicit user ID and password:

```
ENGINE MYSQL SET CONNECTION_ATTRIBUTES TEST/USERA,PWDA
```

The following SET CONNECTION_ATTRIBUTES command connects to the MySQL database server named TEST using password passthru authentication:

```
ENGINE MYSQL SET CONNECTION_ATTRIBUTES TEST/
```

**Authenticating a User**

There are two methods by which a user can be authenticated when connecting to a MySQL database server:

- **Explicit.** User IDs and passwords are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the server global profile, edasprof.prf, for all users.

- **Database or Password Passthru.** User ID and password received from the client application are passed to the MySQL database server for authentication.

When a client connects to the server, the user ID and password are passed to MySQL for authentication and are not authenticated by the server. To implement this type of authentication, start the server with security turned off. The server allows the client connection, and then stores an encrypted form of the client connection message to be used for connection to a MySQL database server at anytime during the lifetime of the server agent.
Overriding the Default Connection

How to:
Select a Connection to Access

Example:
Selecting a Connection to Access

Once all MySQL connections to be accessed have been declared using the SET CONNECTION_ATTRIBUTES command, there are two ways to select a specific MySQL connection from the list of declared connections:

- You can select a default connection using the SET DEFAULT_CONNECTION command. If you do not issue this command, the connection name value specified in the first SET CONNECTION_ATTRIBUTES command is used.

- You can include the CONNECTION= attribute in the Access File of the table specified in the current SQL query. When you include a connection name in the CREATE SYNONYM command from the Web Console, the CONNECTION= attribute is automatically included in the Access File. This attribute supersedes the default connection.

Syntax: How to Select a Connection to Access

```
ENGINE MYSQL SET DEFAULT_CONNECTION [connection]
```

where:

- **MYSQL**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  Is the connection name specified in a previously issued SET CONNECTION_ATTRIBUTES command. If omitted, then the local database server will be set as the default. If this connection name has not been previously declared, a FOC1671 message is issued.

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command will be the active connection name.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, a FOC1671 message is issued.
**Example: Selecting a Connection to Access**

The following SET DEFAULT_CONNECTION command selects the MySQL database server
named TNSNAMEB as the default MySQL database server:

```
ENGINE MYSQL SET DEFAULT_CONNECTION datasource_name
```

**Note:** You must have previously issued a SET CONNECTION_ATTRIBUTES command for the
datasource_name.

**Controlling Connection Scope**

**How to:**
Control the Connection Scope

This topic explains how to set the scope of logical units of work using adapters. This is
accomplished by the SET AUTODISCONNECT command.

A connection occurs at the first interaction with the declared database server.

**Syntax: How to Control the Connection Scope**

```
ENGINE MYSQL SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

MySQL

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE
command.

FIN

Disconnects automatically only after the session has been terminated. FIN is the default
value.

COMMAND

Disconnects automatically after each request. Depending on how often the event occurs,
the SET AUTODISCONNECT command may result in considerable overhead. Almost all
of this overhead is not related to the server. It is related to the operating system and
the data source.

COMMIT

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL
command.
Managing MySQL Metadata

In this section:
Creating Synonyms
MySQL Data Type Support
Changing the Precision and Scale of Numeric Columns
CLOB Activation

This topic describes how to use CREATE SYNONYM for MySQL data sources. It also describes MySQL data type support.

Creating Synonyms

How to:
Create a Synonym

Example:
Sample Generated Synonym

Reference:
Synonym Creation Parameters for MySQL
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each MySQL table or view that is accessible from the server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

**Reference:** Synonym Creation Parameters for MySQL

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Object name**

Selecting this option adds the Object Name parameters to the screen.
Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Location of External SQL Scripts**

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  ```
  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
  ```

  The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
Dynamic columns

To specify that the Master File created for the synonym should not contain column information, select the Dynamic columns check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

For Subquery

Only available when External SQL Scripts is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see MySQL Data Type Support on page 1480.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.
Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for MySQL synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

FILE=DIVISION, SUFFIX=MYSQL,$
SEGNAME=SEG1_4, SEGTYPE=S0,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON,$

Generated Access File nf29004.acx

SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=TEST,KEYS=1, WRITE=YES,$

Reference: Access File Keywords

This chart describes keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the MySQL tablename. The tablename may include owner (schema) name.</td>
</tr>
<tr>
<td></td>
<td>For example,</td>
</tr>
<tr>
<td></td>
<td>TABLENAME=[owner.]tablename</td>
</tr>
<tr>
<td><strong>Keyword</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is:</td>
</tr>
<tr>
<td></td>
<td><code>CONNECTION=connection</code></td>
</tr>
<tr>
<td></td>
<td><code>CONNECTION=''</code> indicates access to the local database server.</td>
</tr>
<tr>
<td></td>
<td>Absence of the <code>CONNECTION</code> attribute indicates access to the default database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first ( n ) fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>KEYFLD IXFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td></td>
<td>- KEYFLD is the FIELDNAME of the common column from the parent table.</td>
</tr>
<tr>
<td></td>
<td>- IXFLD is the FIELDNAME of the common column from the related table.</td>
</tr>
<tr>
<td></td>
<td>KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.</td>
</tr>
<tr>
<td>AUTO_INCREMENT</td>
<td>Set to Yes to enable autoincrementing. (needs explanation)</td>
</tr>
<tr>
<td>START</td>
<td>Initial value in incrementing sequence</td>
</tr>
<tr>
<td>INCREMENT</td>
<td>Increment interval.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).</td>
</tr>
</tbody>
</table>
Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
</tbody>
</table>
| Edit as Text                | Enables you to view and manually edit the Master File synonym.  
**Note:** To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.  |
| Edit Access File as Text    | Enables you to view and manually edit the Access File synonym.  
**Note:** This option is available only when an Access File is created as part of the synonym.     |
| Sample Data                 | Retrieves up to 20 rows from the associated data source.                                                                                   |
| Data Profiling              | Data Profiling provides the data characteristics for synonym columns.  
Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.  
Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.  |
<p>| Refresh Synonym (if applicable) | Regenerates the synonym. Use this option if the underlying object has been altered.                                              |</p>
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the <em>Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual</em> for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**MySQL Data Type Support**

**Reference:**

Data Type Support for Unicode

The following tables describes how the server maps MySQL data types.
### Date-Time Data Types

<table>
<thead>

### Other Data Types
<table>
<thead>
<tr>
<th>MySQL Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENUM('value1', 'value2',......) max of 65535 values</td>
<td>An</td>
<td>$n$ is the maximum length of allowable elements from the list. The ENUM data type is not supported with Connector/J 3.1.14.</td>
</tr>
<tr>
<td>SET ('value1', 'value2',......) max of 64 members</td>
<td>An</td>
<td>$n$ is the length of the value consisting of the values listed in the column definition, separated by commas. The SET data type is not supported with Connector/J prior to 5.1.7.</td>
</tr>
</tbody>
</table>

The following table lists how the non-Unicode server maps Character data types. This mapping can be changed based on the value of LONGCHAR. The default value is ALPHA.

<table>
<thead>
<tr>
<th>MySQL Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR ($m$) $m$ is between 0 and 255</td>
<td>$n$ is an integer between 1 and 255.</td>
<td>$An$</td>
<td>$An$</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$An$</td>
<td>$An$</td>
</tr>
</tbody>
</table>
### Remarks

MySQL Data Type | Remarks |
--- | --- |
VARCHAR (m) | \( n \) is an integer between 1 and 255. \( m \) is between 0 and 65535 |
 | AnV | AnV |
 | TX50 | TX |

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.

**Reference:** Data Type Support for Unicode

The following table describes how the Unicode server maps Character data types. The server operates in character semantic when configured for Unicode. The LONGCHAR does not affect mapping in this case.

<table>
<thead>
<tr>
<th>MySQL Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(m)</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>( m ) is between 0 and 255</td>
<td>( n ) is an integer between 1 and 255.</td>
<td></td>
</tr>
<tr>
<td>VARCHAR (m)</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>( m ) is between 0 and 65535</td>
<td>( n ) is an integer between 1 and 32767. Data beyond 32767 bytes will be truncated.</td>
<td></td>
</tr>
</tbody>
</table>
Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

ENGINE MYSQL SET CONVERSION RESET
ENGINE MYSQL SET CONVERSION format RESET
ENGINE MYSQL SET CONVERSION format [PRECISION precision [scale]]
ENGINE MYSQL SET CONVERSION format [PRECISION MAX]

where:

**MYSQL**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**

Is any valid format supported by the data source. Possible values are:

**INTEGER** which indicates that the command applies only to INTEGER columns.

**DECIMAL** which indicates that the command applies only to DECIMAL columns.

**REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```sql
ENGINE MYSQL SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```sql
ENGINE MYSQL SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```sql
ENGINE MYSQL SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```sql
ENGINE MYSQL SET CONVERSION RESET
```

**CLOB Activation**

**How to:**

Set Server CLOB Activation

The default mapping for MySQL data types CHAR, VARCHAR, VARCHAR2, and RAW is the data type ALPHA. The ALPHA data type maximum supported length is 4096 characters for TABLE/MODIFY and 32768 characters for API applications. It is possible to perform SELECT, INSERT, and UPDATE on columns longer than 256 with these data types without using the server data type CLOB.

**Syntax:** How to Set Server CLOB Activation

To activate the support for the server data type CLOB, you must issue the following command in one of the supported server profiles:

```sql
ENGINE MYSQL SET CONVERSION LONGCHAR TEXT
```

where:

**MYSQL**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
ACTIVATES SUPPORT OF LONG CHARACTER COLUMNS AS CHARACTER LARGE OBJECTS. ALPHA IS THE DEFAULT VALUE.

CUSTOMIZING THE ADAPTER FOR THE MYSQL ENVIRONMENT

**In this section:**
- PASSRECS
- Specifying the Transaction Isolation Level
- Cancelling Long Requests

This topic describes how to set the adapter for the MySQL environment.

**PASSRECS**

**How to:**
Set PASSRECS

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax:** **How to Set PASSRECS**

`ENGINE MYSQL SET PASSRECS {ON|OFF}`

**where:**

**MYSQL**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.
OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

**Specifying the Transaction Isolation Level**

**How to:**
Specify Transaction Isolation Level From a SET Command

You can specify the transaction isolation level from the Web Console or using the SET ISOLATION command.

**Syntax:**

**How to Specify Transaction Isolation Level From a SET Command**

You can specify transaction isolation level by issuing the following command

```bash
ENGINE MYSQL SET ISOLATION {RU|RC|RR|SE}
```

where:

**RU**

Sets the transaction isolation level to Read Uncommitted.

**RC**

Sets the transaction isolation level to Read Committed.

**RR**

Sets the transaction isolation level to Repeatable Read.

**SE**

Sets the transaction isolation level to Serializable Read.

**Cancelling Long Requests**

**How to:**
Cancel Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.
Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose Workspace, Configuration/Monitor, Java Services, DEFAULT. Right-click on DEFAULT and select Agents.

2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select Stop.

Optimization Settings

In this section:
- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields
- Optimizing Requests to Pass Virtual Fields Defined as Constants

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

Optimizing Requests

How to:
Optimize Requests

Example:
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

Reference:
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

SQL MYSQL SET {OPTIMIZATION|SQLJOIN} setting
where:

**MySQL**

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**SQLJOIN**

Is a synonym for OPTIMIZATION.

**setting**

Is the optimization setting. Valid values are as follows:

**ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

**OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.

Both OPTIMIZATION settings produce the same report.

**Example: SQL Requests Passed to the RDBMS With Optimization OFF**

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (\?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL MYSQL SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED

SELECT T1.EID, T1.LN, T1.DPT, T1.CSAL, T1.OJT
FROM 'USER1'.EMPINFO T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.FUNDTRAN T2 WHERE (T2.EID = ?) FOR FETCH ONLY;

Example: SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

SQL MYSQL SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
   SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
   IF DEPARTMENT EQ 'MIS'
END

In a trace operation, you will see the following output:

AGGREGATION DONE ...
   SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
   FROM 'USER1'.EMPINFO T1,'USER1'.FUNDTRAN T2
   WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
   GROUP BY T2.EID,T1.LN
   ORDER BY T2.EID,T1.LN;

Reference: SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.
Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

**How to:**
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

**How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields**

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```
SQL MYSQL SET OPTIFTHENELSE {ON | OFF}
```

where:

**MYSQL**
Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**
Enables IF-THEN-ELSE optimization. This is the default.

**OFF**
Disables IF-THEN-ELSE optimization.
Optimization Settings

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
SQL MYSQL SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN',T1.'FN',T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' ')) AND (T1.'DPT' = 'MIS')))));
```

**Example:** Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
SQL MYSQL SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2 ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END
```
The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
  WHERE (((T1.'LN' = 'SMITH')));
```

```
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
  WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

**Example:**  Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```
SQL MYSQL SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END
```

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```

**Reference:**  SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  
  \[ X = X + 1; \]
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

  **Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.

- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.

- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

  **Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.

- STATIC SQL.

- IF/WHERE DDNAME.

- Partial date selection.

**Optimizing Requests to Pass Virtual Fields Defined as Constants**

**Example:**

- Passing Numeric Constants
- Passing a CHAR Constant
- Passing CHAR and INTEGER Constants

A virtual field defined as a constant is passed directly to an SQL database engine (RDBMS) for optimized processing that takes advantage of RDBMS join, sort, and aggregation capabilities, thus reducing the volume of RDBMS-to-server communication and improving response time. (In prior releases, constants were not passed to the database engine, causing optimization to be turned off.)

Constants in the following formats are passed to the RDBMS: NUMERIC, CHAR, VARCHAR, CHAR/INTEGER combination, and DATE. (Note that a few formats are not passed to the RDBMS. These are CHAR and VARCHAR combination, TIME, and DATETIME.)
When valid constants are passed to an RDBMS engine, a report is calculated based on the defined value(s) and only the calculated subset of records is returned. The extent of data manipulation at the adapter level is limited, thereby improving performance.

**Example: Passing Numeric Constants**

DEFINE FILE SMIX87
INTEGERCONST/I4 = 5
REALCONST/D20.2 = -97995.38
NUMERICCONST/P13.4 = -92999.3647

TABLE FILE SMIX87
SUM INTEGERCONST REALCONST NUMERICCONST MAX.QUOT.FA01INTEGER
BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", SUM(5), SUM(-97995.38),
SUM(-92999.3647), MAX(T2."FA01INTEGER")
FROM TMIX83A T2
GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Example: Passing a CHAR Constant**

DEFINE FILE SMIX87
CHARCONST/A10 = '2N'

TABLE FILE SMIX87
SUM CHARCONST MIN.FA02CHAR_15
BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), MIN(T3."FA02CHAR_15")
FROM TMIX83A T2, TMIX86A T3
WHERE (T3."FA01INTEGER" = T2."FA01INTEGER")
GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Example: Passing CHAR and INTEGER Constants**

DEFINE FILE SMIX87
CHARCONST/A10 = '2N'
INTEGERCONST/I4 = 5

TABLE FILE SMIX87
SUM CHARCONST INTEGERCONST
BY QUOT.FA02INTEGER
END
The following SQL is generated:

```sql
SELECT T2."FA02INTEGER", MAX('2N'), SUM(5) FROM TMIX83A T2
GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```
The Adapter for NATURAL enables a client to execute a NATURAL program that receives and returns data via NATURAL work files. The adapter can be executed on USS, UNIX, and Windows platforms.

**Topics:**
- Preparing the NATURAL Environment
- Configuring the Adapter for NATURAL
- Managing Metadata for NATURAL
- Invoking a NATURAL Program
Preparing the NATURAL Environment

In this section:
- Modifying Model Files
- Setting Up the NATURAL Environment
- Maintaining the NATURAL Parameter File on Windows and UNIX

In order to be able to access Adabas databases from Natural programs, you must set up the Adabas environment. For details, see Using the Adapter for Adabas on page 119.

You must then perform several operating system-specific tasks to set up the Natural environment itself.

Modifying Model Files

**z/OS:**

Model files with the jcl extension are supplied in the `home/etc` directory. They contain jobs to be executed on the mainframe. You must modify these file by supplying correct values in all lines marked with `<--` characters.

- **IWAYNATB.** Installs the supporting NATURAL program IWAYNATB in the Adabas NATURAL file that contains library SYSEXT. This program is used in synonym creation.
  
  You can change the library and/or program name. However, the new name(s) must be changed correspondingly in the natbdbs.acx file.

  If you choose a non-SYSEXT library, you must either place the SYSEXT library in the NATURAL profile steplib list or concatenate the new library with the SYSEXT library.

- **IWAYIVPB.** Installs the example NATURAL program IWAYIVPB and local data areas. IWAYTSTI/IWAYTSTO define input/output buffers processed by the program. You can install these NATURAL objects in any NATURAL library.

  You can change the program name, however, if you rename data areas, you must change the names correspondingly in the program IWAYIVPB source code. These objects are used to verify synonym creation.

**Windows and UNIX:**

Model files with the natural extension are supplied in the `home/etc` directory. These files must be processed by the SAG NATURAL utility SYSTRANS.

- **IWAYNATB.** You must install the Natural program in the library SYSEXT. This program is used in synonym creation.
You can change the library and/or program name. However, the new name(s) must be changed correspondingly in the natb dbs.acx file.

If you choose a non-SYSEXT library, you must either place the SYSEXT library in the NATURAL profile steplib list or concatenate the new library with the SYSEXT library.

- **IWAYIVPB.** You must install the Natural program along with the supporting data areas to any library (SYSTEM is default). IWAYTSTI/IWAYTSTO data areas define input/output buffers processed by the program.

You can change the program name, however, if you rename data areas, you must change the names correspondingly in the program IWAYIVPB source code. These objects are used to verify synonym creation.

### Setting Up the NATURAL Environment

**On z/OS:**

Prior to configuring the Adapter for NATURAL using the Web Console, you must edit the IRUNJCL that is used to initiate the server by allocating the following database and Natural load libraries to the server STEPLIB:

```
//IRUNJCL     PROC
//STEPLIB DD DISP=SHR, DSN=EDABXV.SRV71.HOME.LOAD
//         DD DISP=SHR, DSN=SAGLIB.NAT314.LOAD
//         DD DISP=SHR, DSN=ADABAS.V742.LOAD
```

Alternatively, if the server is started from USS using edastart, export STEPLIB from the edastart file, as follows:

```
export STEPLIB=SAGLIB.NAT314.LOAD:ADABAS.V713.LOAD
```

**On Windows:**

Add Natural directory to the PATH.

**On UNIX:**

Execute the `sagenv` script as follows to set the environment:

```
. <SAG-root-directory>/sagenv
```

Either sagenv or sagenv.new is generated during Natural installation and setup. For details, refer to the SoftwareAG Natural documentation.

### Maintaining the NATURAL Parameter File on Windows and UNIX

Use the SAG-provided utility, natparm, to maintain the NATURAL parameter file. It is good practice to create a copy of the standard system parameter file and use this copy to run the adapter. The name of the new file is stored as part of the connection information.
The parameter file must contain the following data channels and work file definitions:

**Input Data Channels:**
- value for CMOBJIN - %EDATEMP%\cmsynin
- value for CMSYNIN - %EDATEMP%\cmsynin
- value for CMPRINT - %EDATEMP%\cmprint

**Work Files:**
- value for CMWKF31 - %EDATEMP%\cmwkf31 (Type=SAG)
- value for CMWKF32 - %EDATEMP%\cmwkf32 (Type=SAG)

You must set the parameter ENDMSG ON to verify the Natural program execution.

### Configuring the Adapter for NATURAL

**In this section:**
- Declaring Connection Attributes

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Declaring Connection Attributes

How to:
Declaring Connection Attributes
Declaring Connection Attributes Manually

Example:
Sample Connection Declarations

Reference:
Connection Attributes for NATURAL
System-Specific Usage Notes

In order to connect to NATURAL, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one data source by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to NATURAL takes place when the first query that references that connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
or

From the Data Management Console, expand the Adapters folder.
The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: **Connection Attributes for NATURAL**

The NATURAL Batch adapter is under the Procedures group folder.
The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**Natural driver**

Is the name of the NATURAL driver. This required value is installation dependent.

**Security**

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.
User

Password

Is the password associated with the user name. This field is only displayed when the security mode of the server is non-trusted.

Natural Session Parameters

NATURAL session dynamic parameters (system specific). These parameters are required:

- FDIC is a system file containing cross-reference information and DDMs. If Predict is installed at your site, FDIC is the Predict dictionary file. If Predict is not installed at your site, FDIC is identical to either FNAT or FUSER and on the mainframe contains DDMs only. FDIC is specified with the FDIC profile parameter. FDIC includes two parameters with the values Database number and File number.

- INTENS. For related information, see System-Specific Usage Notes on page 1506.

See your Natural Reference documentation for details.

Adabas Session Parameters

On USS platforms, these parameters are usually provided in the DDCARD DD statement. They include four parameters: database number, device type, SVC number, and MODE. See the Software AG documentation for details.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

Explicit authentication. The user ID and password are explicitly specified for each connection and passed to NATURAL, at connection time, for authentication.

ENGINE NATB SET CONNECTION_ATTRIBUTES [connection]/userid,password: "parameters_list"

Password passthru authentication. The user ID and password are explicitly specified for each connection and passed to NATURAL CICS, at connection time, for authentication.

ENGINE NATB SET CONNECTION_ATTRIBUTES [connection]/: "parameters_list"
Trusted. The adapter connects to NATURAL as an operating system login using the credentials of the operating system user impersonated by the server data access agent.

ENGINE NATB SET CONNECTION_ATTRIBUTES [connection]/,: "parameters_list"

where:

NATB

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is a logical name used to identify this particular set of connection attributes. In the Access File, it becomes the CONNECTION=connection_name value. For details, see Access File Attributes on page 1518.

userid

Is the primary authorization ID by which you are known to the Adapter for NATURAL.

password

Is the password associated with the primary authorization ID.

parameters_list

The following parameters are supported (some optional and some required):

natnuc_name is the name of the NATURAL driver. This required parameter is NATURAL installation dependent.

natuser_id is the userid for NATURAL security. This parameter is optional.

natpwsd_pswd is the password for NATURAL security. This parameter is optional.

'natparm_value' is the NATURAL session dynamic parameters (system specific). These parameters are required. For details, see System-Specific Usage Notes on page 1506.

'adaparm_value' is applicable only on USS platforms, ADABAS session parameters, usually provided in the DDCARD DD statement, include four parameters: database#, device type, SVC#, and MODE. See the Software AG documentation for details.

Reference: System-Specific Usage Notes

- On z/OS, the NATPARM value contains parameters usually provided in the PARM parameter of the EXEC statement for the NATURAL Batch driver. For details, consult the NATURAL DBA. Providing the parameter INTENS=1 is highly recommended.

- On Windows, the NATPARM value contains dynamic parameters accepted by NATURAL in batch mode. For details, see the SAG documentation.
In addition, a list of parameters may provide the name of the NATURAL parameter file in the form PARM=filename. The PARM parameter is mandatory if the file name is different from natparm. The parameter file is created and maintained by the SAG provided program natparm, as described in *Preparing the NATURAL Environment* on page 1500.

- In UNIX, the NATPARM value contains the same information as on Windows, but, in addition, it may contain a buffer pool name in form BP=name. For information on Buffer pool usage, see the SAG documentation.

**Example:**  
**Sample Connection Declarations**

**Windows:**

```plaintext
ENGINE NATB SET CONNECTION_ATTRIBUTES CON3 /,: "NATNUC natural NATPARM 'PARM=IWAYPARM'"
```

**UNIX:**

```plaintext
ENGINE NATB SET CONNECTION_ATTRIBUTES CON3 /,: "NATNUC natural NATPARM 'PARM=IWAYPARM BP=NATBP'"
```

**z/OS:**

```plaintext
ENGINE NATB SET CONNECTION_ATTRIBUTES CON3 /,: "NATNUC NAT314BA NATPARM 'FDIC=(,21),INTENS=1' ADAPARM 'ADARUN DB=003,DE=3390,SVC=240,MODE=MULTI'"
```

**Managing Metadata for NATURAL**

**In this section:**

Creating Synonyms

When the adapter invokes a Natural program, it needs to know where to find the program and how to process its parameters. For each Natural program the adapter will access, you create a synonym that describes this information.
Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Creating a Synonym

**Reference:**
Synonym Creation Parameters for NATURAL
Managing Synonyms
Programming Requirements for NATURAL
Master File Attributes
Access File Attributes

A synonym defines a unique logical name (also known as an alias) for each Natural file, and one set of input/output parameters. The adapter requires that you generate a synonym for each Natural file you want to invoke with the adapter.

Synonyms define unique names (or aliases) for each transaction or procedure that is accessible from the server. Synonyms are useful because they hide the underlying transaction or procedure from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Creating a synonym generates a Master File and an Access File. These are metadata that describe to the server the Natural program name, parameters, and options.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click **Applications**.
   The Applications page opens.

2. Click the **New** button and select **Synonym** from the drop-down menu.
   The **Select adapter to configure or Select connection to create synonym** pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.
4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting **Create Synonym**.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see **Validation for Special Characters and Reserved Words** on page 2821.

**Reference:** Synonym Creation Parameters for NATURAL

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the **Create Synonym** button, which generates the synonym based on your entries.

**Natural System/User file with program libraries:**

**Data base ID**

The database ID.

**File number**

**File password**

If set, the password associated with the Natural system file.

**Mask for library names**

Natural library with Natural programs.

Enter a string for filtering library names, inserting the wildcard character (%) at the beginning and/or end of the string.

For example, enter ABC% to display libraries whose names begin with the letters ABC; %ABC to display libraries whose names end with the letters ABC; %ABC% to display libraries whose names contain the letters ABC at the beginning, middle, or end; or % to display all libraries.
**Mask for program names**

The mask for returning a list of program names from which to chose. Enter a string for filtering program names, inserting the wildcard character (%) at the beginning and/or end of the string.

**Program names**

Choose a program from the drop-down list.

**No data area available**

Check this box if your data is defined in either a local data area or a parameter data area. For more information, see the Software AG documentation on data area.

**Note:** If you check this box, you are re-prompted for database, file and password information on the next Create Synonym pane.

Leave this box unchecked if you are not using defined data.

**Natural System/User file with data area definitions:**

**Data base ID**

The database ID.

**File number**

A number that identifies the Natural System user file.

**File password**

If set, the password associated with the Natural system file.

**Mask for the library names**

The mask for returning a list of libraries from which to chose the one containing local/global data areas that describe the program parameters.

**Mask for the Data Area names**

Enter the mask for returning a list of the data areas from which you will chose the data area defining the program parameters.

**Natural library**

Select a library from the drop-down list.

**Synonym name**

The name of the synonym. You can retain the current name or change it.

Changing a synonym’s name enables you to manage multiple synonym versions to reflect, for example, multiple environments, or synonyms with different application logic such as different sets of Master File DEFINE attributes.
Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Input Data Area/Output Data Area

Specifies which data area's are for input parameters and which are for output parameters. You can specify the same data area as the source of both the input and output parameters.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>

<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Reference: Programming Requirements for NATURAL**

To be invoked from the adapter, a NATURAL program must conform to the following rules:

- Program must read input parameters from the work file number 31.
- Program must write output data in the work file number 32.
- On USS platforms, the input parameter record is prefixed with the 2-byte length binary prefix containing the record length (excluding prefix itself).
- On USS platforms, each output record must be prefixed with the 2-byte length binary prefix containing the record length (excluding prefix itself). For example
  
  ```
  WRITE WORK FILE 32 VARIABLE #LEN MEM-LIST
  ```
  
  where:
  
  ```
  #LEN(I2)
  ```
  
  Contains the length of the structure MEM-LIST.

- On Windows and UNIX, the work files must be described in the Natural parameter file with type SAG. For related information, see *Preparing the NATURAL Environment* on page 1500.

**Example: Creating a Synonym**

The following example includes a NATURAL program and local data areas, with corresponding metadata.

```naturalsource

To generate a synonym for the NATURAL program IWAYIVPB, enter the following information on the Create Synonym panes of the Web Console or the Data Management Console:

1. On the first Create Synonym pane, enter 3 in the Database ID field, enter 9 in the File number field, and enter the password associated with the Natural system file in the File password field. Enter SYS% as a mask to filter library names.

2. On the second pane, enter IWAY% to filter program names, select SYSTEM from the drop-down library list, and click Next.

3. On the third pane, choose IWAYIVPB from the drop-down list of programs. Leave No data area available unchecked since the data in this example is defined in a local data area. Click Next.

4. On the fourth pane, once again enter 3 in the Database ID field, enter 9 in the File number field, and enter the File password. Enter SYS% to filter library names, and click Next.

5. On the fifth pane, enter IWAY% to filter data area names, and choose SYSTEM from library the drop-down list. Click Next.

6. On the final Create Synonym pane, select IWAYTSTI from the list of Input Data Areas. Select IWAYTSTO from the list of Output Data Areas.

7. Click Create Synonym. The synonym is created and added under the specified application directory (baseapp is the default).

A status window displays the message: All Synonyms Created Successfully

8. From the message window, click Applications on the menu bar.

9. Open the baseapp application folder in the navigation pane and click the synonym IWAYIVPB.

10. Choose Edit as Text from the menu to view the generated Master File, then choose Edit Access File as Text to view the corresponding Access File.
**Generated Master File**

</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Is the name of the input segment in the Master File.</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates the connection_name as previously specified in a SET CONNECTION_ATTRIBUTES command. Defaults to the default connection.</td>
</tr>
<tr>
<td>TRANSACTION</td>
<td>Is the name of the library:program to be executed.</td>
</tr>
</tbody>
</table>
Invoking a NATURAL Program

**How to:**
- Invoke a NATURAL Program Using TABLE
- Invoke a NATURAL Program Using SELECT
- Invoke a NATURAL Program Using EX

**Example:**
- Invoking the Natural Program NATTST Using TABLE
- Invoking the Natural Program NATTST Using SQL SELECT
- Invoking the Natural Program NATTST Using EX

To invoke a Natural program, you issue a a Data Manipulation Language (DML) request, also known as a TABLE command, or an SQL SELECT statement. (DML is the WebFOCUS internal retrieval language.) For information about the Data Manipulation Language, see the Stored Procedure Reference manual.

**Syntax:** **How to Invoke a NATURAL Program Using TABLE**

The syntax for invoking a Natural program using a TABLE command is

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
  ...
  ...
END
```

where:

- **synonym**
  - Is the synonym of the Natural program you want to invoke.

- **parameter**
  - Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.

  If the stored procedure does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.
Invoking a NATURAL Program

* Indicates that you want to display all indicated parameters.

**IF/WHERE**

Is used if you want to pass values to input parameters.

* **in-parameter**

Is the name of an input parameter to which you want to pass a value.

* **value**

Is the value you are passing to an input parameter.

**Example:** Invoking the Natural Program NATTST Using TABLE

```
TABLE FILE NATTST
PRINT PERSONNEL_ID NAME BIRTH SALARY
IF PERSONNEL_ID_FROM EQ '11111111'
IF PERSONNEL_ID_TO EQ '11211111'
IF SALARY NE 0
END
```

**Syntax:** How to Invoke a NATURAL Program Using SELECT

The syntax for invoking a Natural program using a SELECT statement is

```
SQL
SELECT [parameter [,parameter] ... | *) FROM synonym
[WHERE in-parameter = value]
.
.
.
END
```

where:

* **synonym**

Is the synonym of the Natural program you want to invoke.

* **parameter**

Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.
Indicates that you want to display all indicated parameters.

WHERE

Is used if you want to pass values to input parameters.

You must specify the value of each parameter on a separate line.

in-parameter

Is the name of an input parameter to which you want to pass a value.

value

Is the value you are passing to an input parameter.

**Example:** **Invoking the Natural Program NATTST Using SQL SELECT**

```sql
SELECT PERSONNEL_ID, NAME, BIRTH, SALARY
FROM NATTST
WHERE PERSONNEL_ID_FROM = '11111111' AND
PERSONNEL_ID_TO = '11211111' AND
SALARY != 0;
END
```

**Syntax:** **How to Invoke a NATURAL Program Using EX**

```ex
EX [app_name_space/]synonym 1=parm1_val,..., N=parmN_val
EX [app_name_space/]synonym parm1_name=parm1_val,...,
parmN_name=parmN_val
EX [app_name_space/]synonym [, parm1_val [{...[, parmN_val]]}]
```

where:

**app_name_space**

Is the apps directory name under which the synonyms are stored. This value is optional.

**synonym**

Is the user-friendly name of a repository entry that represents the object to be executed in the vendor environment.

**parm_name**

Is the name of the parameter taken from the input metadata description.
Invoking a NATURAL Program

\[ I_{parm1_val} \]
\[ N_{parmN_val} \]
\[ parm1\_name \]
\[ parm1\_val \]
\[ parmN\_val \]

Are the parameter values that match the input metadata description.

**Note:**

- Consecutive commas denote missing parameters in the positional form of the request.
- Values containing special characters (<equal sign> <space> <comma>) must be encapsulated in double or single quotation marks.

**Example:** Invoking the Natural Program NATTST Using EX

```
SET EXORDER=PGM/FEX
EX NATTST 11111111, 11211111
```
45 Using the Adapter for NATURAL CICS Transactions

The Adapter for NATURAL CICS Transactions enables a client to execute a NATURAL program that receives and returns data using the Reporting Server API.

This adapter supports the following transport layers:

- EXCI for z/OS platforms.
- TCP62 through AnyNET for UNIX and Microsoft Windows platforms.
- TCP/IP for UNIX, Microsoft Windows, and z/OS platforms.
- LU6.2 for UNIX, Microsoft Windows, and z/OS platforms.

Topics:
- Preparing the CICS Environment
- Supported Platforms and Release Information
- CICS and VTAM Configuration
- Installing NATURAL Support Programs
- Configuring the Adapter for NATURAL CICS Transactions
- Managing NATURAL CICS Transactions Metadata
- NATURAL Data Buffer Processing API
- Invoking a NATURAL CICS Transaction
Preparing the CICS Environment

The following diagram shows the basic flow of a CICS transaction. It illustrates how the client application communicates with the adapter.

The communication to the NATURAL CICS Transactions region depends upon the platform the adapter is running on. If you are using UNIX or Microsoft Windows, you can use a communication transport of TCP 62 (AnyNET) for DPL programs or LU6.2 for APPC programs. If you are using z/OS, a direct NATURAL CICS Transactions External Call Interface is used for DPL programs (use of LU6.2 for APPC programs from z/OS is not supported in this release of the server).

To provide for transparent execution of NATURAL CICS Transactions programs, metadata describing the program input and output areas is held on the server. For DPL programs, the Natural Data Area describing DFHCOMMAREA is used as a source for metadata creation. For APPC-based programs, the Natural Data Area describing the storage layout for NATURAL CICS Transactions SEND and RECEIVE calls is used as a source for metadata creation: RECEIVE for input; SEND for output.

You can use the Web Console or the Data Management Console for configuration and to create/maintain the metadata associated with the programs to be executed. You can also use the Web Console to add or change adapter communication parameters.
Supported Platforms and Release Information

The following platforms are supported: Microsoft Windows, UNIX, and z/OS.

For Microsoft Windows and UNIX based servers that use AnyNET or LU6.2 to communicate with any NATURAL CICS Transactions region, the following minimum software release levels on a target are required:

- z/OS Version 1.1 or higher
- NATURAL CICS Version 4 or higher
- TCP/IP Direct Access, CICS TS2.3 or higher

**Note:** To use TCP62 or AnyNET, all VTAM options for AnyNET must be configured and AnyNET must be active.

For z/OS based servers, the following minimum software release levels are required:

- z/OS Version 1.1 or higher
- NATURAL CICS Version 4 or higher

**Note:** Because the EXCI option is being used, the adapter can only communicate with NATURAL CICS Transactions regions that are running on the same LPAR. Also, the STEPLIB of the EDASTART JCL member of the configuration data set needs to include the NATURAL CICS Transactions SDFHEXCI library.

CICS and VTAM Configuration

**In this section:**
- AnyNET VTAM Definitions
- LU6.2 VTAM Definitions
- CICS Connection and Sessions for Microsoft Windows and UNIX

These topics provide the setup and communications configuration information the adapter requires to communicate with NATURAL CICS Transactions.

After you configure any VTAM definitions, the major nodes they describe need to be started in the VTAM system. If you are using AnyNET, it should be tested from the Adapter for NATURAL CICS Transactions platform.
AnyNET VTAM Definitions

The AnyNET product requires three major VTAM nodes for its operation. The main node for AnyNET identifies the port. The following are examples of the three nodes. Replace relevant parameters with your site specific values.

Example: Setting Up the Major Node for the AnyNET Listener

```
**********  TCP62 MAJOR NODE DEFINITION FOR ANYNET
TCP62   VBUILD TYPE=TCP,DNSUFX=IBI.COM,PORT=397
TCP62G  GROUP  ISTATUS=ACTIVE
TCP62L  LINE   ISTATUS=ACTIVE
TCP62P  PU     ISTATUS=ACTIVE,NETID=MYNET
```

**Note:** Port 397 is used in this example. On UNIX, using a port number above 1000 is recommended due to the root privileges associated with using a port number under 1000. On z/OS, 397 is the default port; it is well established and frequently used.

Keep in mind, however, that the port you use must be the same on UNIX and z/OS. For example, if 1000 is specified on one platform, it must also be specified on the other.

Example: Setting Up the Major Node for Cross Domain Resources

If CDRDYN=YES is not specified in the ATCSTR00 VTAM startup parameter file, then the name of the machine that the Transaction Adapter is running on needs to be coded in the follow node:

```
VBUILD TYPE=CDRSC
CDRSC62 NETWORK NETID=MYNET
CDRSC62 GROUP
EDABGR2 CDRSC ALSLIST=TCP62P
```

**Note:** EDABGR2 is the machine name on which the server is running. The machine name must be limited to eight bytes.
Example: Setting Up the Standard VTAM LU Definitions

```plaintext
VBUILD TYPE=SWNET
MYNAMEPU PU ADDR=01, IDBLK=05D, IDNUM=10101, X
  MAXPATH=3, X
  PTYPE=2, X
  MODETAB=MTOS2EE, X
  DLOGMOD=PARALLEL, X
  ISTATUS=ACTIVE
MYLUNAME LU LOCADDR=2
```

LU6.2 VTAM Definitions

Example: Setting Up the Major Node for the AnyNET Listener

**Setting Up the Standard VTAM LU Definitions**

LU6.2 requires two major VTAM nodes for its operation. The main node for AnyNET identifies the port. The following are examples of these two nodes. Replace relevant parameters with your site specific values.

Example: Setting Up the Major Node for the AnyNET Listener

```plaintext
********** TCP62 MAJOR NODE DEFINITION FOR ANYNET
TCP62 VBUILD TYPE=TCP, DNSUFX=IBI.COM, PORT=397
TCP62G GROUP ISTATUS=ACTIVE
TCP62L LINE ISTATUS=ACTIVE
TCP62P PU ISTATUS=ACTIVE, NETID=MYNET
```

**Note:** Port 397 is used in this example. On UNIX, using a port number above 1000 is recommended due to the root privileges associated with using a port number under 1000. On z/OS, 397 is the default port; it is well established and frequently used.

Keep in mind, however, that the port you use must be the same on UNIX and z/OS. For example, if 1000 is specified on one platform, it must also be specified on the other.

Example: Setting Up the Standard VTAM LU Definitions

```plaintext
VBUILD TYPE=SWNET
MYNAMEPU PU ADDR=01, IDBLK=05D, IDNUM=10101, X
  MAXPATH=3, X
  PTYPE=2, X
  MODETAB=MTOS2EE, X
  DLOGMOD=PARALLEL, X
  ISTATUS=ACTIVE
MYLUNAME LU LOCADDR=2
```
CICS Connection and Sessions for Microsoft Windows and UNIX

**Example:**
Using the CEDA View Connection Command
Using the CEDA View Sessions Command

For the Adapter for NATURAL CICS Transactions to be able to connect to NATURAL CICS Transactions (for both TCP62 and LU6.2 where supported), Connection and Session definitions are required. The definitions are dependent on the platform on which the adapter is running.

If you deploy the adapter on Microsoft Windows or UNIX, the connection and sessions definitions described in *Using the CEDA View Connection Command* on page 1528 and *Using the CEDA View Sessions Command* on page 1528 are required.

**Note:** For DPL program execution, all users must be able to access and run transaction CPMI (the mirror transaction).

**Example:** **Using the CEDA View Connection Command**

The following is an example of a CEDA view connection command that illustrates what is required:

CEDA View Connection( MYLU )
  Connection : MYLU
  Netname     : MYLUNAME
  Accessmethod: Vtam  Vtam | IRc | INdirect | Xm
  Protocol    : Appc  Appc | Lu61 | Exci
  Singlesess  : No    No | Yes
  Datastream  : User  User | 3270 | SCs | Strfield | Lms
  InService   : Yes   Yes | No
  Attachsec   : Verify Local | Identify | Verify | Persistent

**Example:** **Using the CEDA View Sessions Command**

The following is an example of a CEDA view sessions command that illustrates what is required:

CEDA View Sessions( MYLUNAME )
  Sessions    : MYLUNAME
  Connection  : MYLU
  Modename    : PARALLEL
  Protocol    : Appc  Appc | Lu61
  Maximum     : 008 , 000 0-999
The MAXimum parameter determines the number of concurrent sessions available to process requests. Its first value should be in the range of 4 - 255, and the second one should always be set to zero.

**Note:** Log mode must support parallel sessions.

## Installing NATURAL Support Programs

Three model files with the jcl extension are supplied in the home/etc directory. You must modify these files and correct values supplied in all lines marked with `--` character, and install them.

- **IWAYCICN.** This file contains the job to be executed on the mainframe to install a proxy transaction and the supporting run-time programs, AASNATC and AASSUBC, in CICS. You can change the Proxy transaction name. The new name will be used in the NATPROXY parameter when connection to CICS NATURAL is configured.

- **IWAYNATC.** This file contains the job to be executed on the mainframe to install the supporting NATURAL program IWAYNATC in the ADABAS NATURAL file containing library SYSEX. These programs are used in metadata processing. You can change the library and/or program names. However, you must change the names correspondingly in the natclics.acx file. If you choose a non-SYSEX library, you must either place the SYSEX library in the NATURAL profile steplib list or concatenate the new library with the SYSEX library.

- **IWAYIVPD.** This file contains the job to be executed on the mainframe to install the sample NATURAL program IWAYIVPD and the local data areas. IWAYTSTI and IWAYTSTO define input and output buffers processed by the program. You can install these NATURAL objects in any NATURAL library. You can change the program name. However, renaming of data areas requires corresponding changes in the program IWAYIVPD source code. These object names are used to verify synonym creation.

## Configuring the Adapter for NATURAL CICS Transactions

**In this section:**

- Configuring Communications Parameters for TCP 62 and LU 6.2
- Declaring Connection Attributes
- Configuring the Adapter on Microsoft Windows and UNIX
- Configuring the Adapter on z/OS

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish. In addition, for if you are using the TCP 62 or LU 6.2 communication protocols, you must configure a Listener node.
Configuring Communications Parameters for TCP 62 and LU 6.2

How to: Configure a Listener

Example:
Sample Node Definitions Using LU6.2
Sample Node Definitions Using TCP/IP (TCP 6.2)

Reference:
Communications Parameters for CICS Transactions for TCP 62 or LU 6.2

This procedure is required if you are using TCP 62 or LU 6.2 as your communications protocol. Note that you can complete this step either before or after you declare connection attributes.

Procedure: How to Configure a Listener

Note: This step is required if you are using TCP 62 or LU 6.2 on Windows or UNIX.

1. From the Web Console menu bar, select Workspace, then Configuration.

2. On the expanded menu bar, select New, then Listener, and CICST. The Listener Configuration pane opens.

3. Type the appropriate values for the communications parameter.

   For descriptions of these parameters, see Communications Parameters for CICS Transactions for TCP 62 or LU 6.2 on page 1530.

   Tip: You can also obtain details about each entry by clicking the ? icon to the left of any parameter field on the communications configuration pane to access the Web Console Help.

4. Click Save and Restart.

Reference: Communications Parameters for CICS Transactions for TCP 62 or LU 6.2

This chart describes the parameters required to configure communications. To complete the configuration, click Save and Restart Listener.
<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE</td>
<td>8-character string</td>
</tr>
<tr>
<td></td>
<td>Defines a logical name of a node block, which must be unique in the file. The logical name can be a maximum of 8 characters, must begin with a letter, and can include any characters, except semicolon and equal sign. A node block contains keyword-value pairs, which are enclosed in a BEGIN-END statement.</td>
</tr>
<tr>
<td>PARTNER_LU_NAME</td>
<td>string</td>
</tr>
<tr>
<td></td>
<td>Defines the APPLID of the target CICS region.</td>
</tr>
<tr>
<td>LOCAL_LU_NAME</td>
<td>string</td>
</tr>
<tr>
<td></td>
<td>Defines the LU name to be used. This value is taken from an LU entry in the major node. The value is also specified in the CICS connection/sessions definition.</td>
</tr>
<tr>
<td>MODE_NAME</td>
<td>string</td>
</tr>
<tr>
<td></td>
<td>Defines the DLOGMODE parameter value.</td>
</tr>
<tr>
<td>CODEPAGE</td>
<td>string</td>

### Configuring the Adapter for NATURAL CICS Transactions

<table>
<thead>
<tr>
<th><strong>Keyword</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
</table>
| CONNECT_LIMIT       | number of seconds
                      Defines the maximum time, in seconds, that the client waits for a connection response from the AnyNET environment.
                      Provide a value greater than 0. (Do not enter a value of -1.)                                                                                   |
| PROXY               | string
                      Defines the name of the supplied proxy (user-written) program, which converts the Full-Function Server calling syntax to the syntax that is valid for the CICS program to be executed.
                      This parameter is optional, and should be left blank for normal operations. Use it only at the direction of your local support personnel.|
| MIRROR              | string
                      Defines the IBM-supplied mirror transaction CPMI that the Adapter for CICS Transactions calls by default. If this transaction cannot be used, you can create another transaction name to point to the IBM-supplied mirror program DFHMIRS. Enter the alternate name in the MIRROR field. |
| NATPROG             | string
                      Identifies the NATURAL program to be executed.
                      **Note:** This option does not apply to the Adapter for CICS Transactions.                                                                       |
| HOST                | string
                      Defines the host that a client is connecting to or an IP address that a listener is listening on.                                                |
| SERVER_ID           | string
                      Defines the machine name where the server is configured with the CICS AGENT NODE (Listener).                                                    |
| ANYNET_PORT         | positive integer number
                      Defines the port number that the AnyNET product is using. The default AnyNET port is 397, but any number can be used. For UNIX installations, a port number above 1000 is recommended. |
**Additional required information for LU6.2**

<table>
<thead>
<tr>
<th><strong>Keyword</strong></th>
<th><strong>Description</strong></th>

   HOST = SPGCSRV
   CODEPAGE = 037
   COMMUNICATION = TCP
   VTAM_NETWORK_ID = USIBINET
   CONNECT_LIMIT = 60
   MIRROR = CPMI
   ATTACH_SECURITY = VERIFY
   SECURITY = C2B591CC2A92650028E8A570F3BE36F3
END
```

**Declaring Connection Attributes**

In order to connect to NATURAL CICS Transactions, the adapter requires connection and authentication information. You supply this information using the `SET CONNECTION_ATTRIBUTES` command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (`user.prf`), or a group profile (if supported on your platform).
Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one data source by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to NATURAL CICS Transactions takes place when the first query that references that connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

For detailed instructions about declaring connection attributes for your operating system, see Configuring the Adapter on Microsoft Windows and UNIX on page 1535 or Configuring the Adapter on z/OS on page 1539.

Configuring the Adapter on Microsoft Windows and UNIX

**How to:**
Declare Connection Attributes on Windows and UNIX
Declare Connection Attributes Manually on Windows and UNIX

**Reference:**
Connection Attributes for NATURAL CICS Transactions on Windows and UNIX

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish. In addition, if you are using the TCP 6.2 or LU 6.2 communications protocol, you must configure a Listener node as described in How to Configure a Listener on page 1530. For TCP/IP, you only need to declare connection attributes.

**Procedure: How to Declare Connection Attributes on Windows and UNIX**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters
   or
   from the Data Management Console, expand the Adapters folder.
   The Adapters folder opens.
2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right click the adapter name/version and select Configure.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter as described in the connection attributes reference.

   For TCP/IP, the configuration parameters for the adapter are displayed.

   For TCP 62 and LU 6.2, you are prompted to either Configure CICST listener or to click Next to display the configuration parameters for the adapter. You can complete these tasks in either order, but both must be done to use the adapter.

   - If you click Next, the configuration parameters are displayed. However, in this scenario, you must then configure a Listener node, as described in How to Configure a Listener on page 1530.

   - If you click Configure CICST listener, the Web Console opens at the Special Services pane. For instructions, see How to Configure a Listener on page 1530.

     Once you have configured the Listener, return to the Add CICS Transaction for Natural to Configuration pane, where the Listener node is now available for selection.

7. Enter values for the parameters required by the adapter as described in the connection attributes reference.

8. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

**Reference:** **Connection Attributes for NATURAL CICS Transactions on Windows and UNIX**

The CICS Transaction for Natural adapter is under the Procedures group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

**Communication Protocol**

Select one of the following: TCP/IP, TCP 62, LU 6.2. Subsequent options vary slightly depending on this selection.

**Note:** For TCP 62 and LU 6.2, you must How to Configure a Listener on page 1530 either before or after you declare connection attributes.
This selection is reflected in the Communication field on the second configuration pane.

**Connection name**
Is a logical name used to identify a specific set of connection attributes.

**Node name**
For TCP 62 or LU 6.2, a drop-down list of nodes is displayed if the Listener has already been configured. Select a node from the list.

**Host name**
For TCP/IP, enter the name of the host machine.

**Application ID**
For TCP 62 or LU 6.2, enter the application ID of the CICS Transactions region.

**Mirror**
Enter the name of the mirror transaction.

**Port**
For TCP/IP, enter the port number.

**Proxy**
Enter the name of a proxy program in NATURAL CICS. The default value is AASNATC. This value overwrites the PROXY parameter value provided when the Listener is configured.

**Natural driver**
Enter the name of the NATURAL nucleus in CICS. This value is NATURAL CICS-dependent.

**Security**
There are two methods by which a user can be authenticated when connecting:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the adapter, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to the adapter, at connection time, for authentication.

**User**
Is the user name by which you are known to the adapter. This field is only displayed when the security mode of the server is non-trusted.
**Password**

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:** How to Declare Connection Attributes Manually on Windows and UNIX

**Explicit.** The user ID and password are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the server global profile, edasprof.prf, for all users:

ENGINE NATCICS SET CONNECTION_ATTRIBUTES [connection] [node_name]/userid,password: "parameters_list"

**Password passthru.** The user ID and password are explicitly specified for each connection and passed to CICS Transactions, at connection time, for authentication.

ENGINE NATCICS SET CONNECTION_ATTRIBUTES [connection] [node_name] /: "parameters_list"

where:

NATCICS
- Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection
- Is a logical name used to identify this particular set of connection attributes. In the Access File, it becomes the CONNECTION=connection_name value. See Access File Attributes on page 1552.

node_name
- Is a name of the NODE definition in the ODIN configuration file.

userid
- Is the primary authorization ID by which you are known to the Adapter for NATURAL CICS Transactions.

password
- Is the password associated with the primary authorization ID.
The following parameters are supported (some required; some optional):

- **application_ID** is the application ID of the CICS region. This parameter is optional.
- **mirror_name** is the name of the mirror transaction. This value overwrites the MIRROR value provided when the Listener is configured. This parameter is optional.
- **communication** is the communication protocol being used. The options are: TCP/IP, TCP 6.2 (AnyNET), and LU 6.2.
- **natnuc_name** is the name of the NATURAL nucleus in CICS. This value is NATURAL CICS-dependent. This parameter is required.
- **natproxy_name** is the name of proxy program in CICS. The default value is AASNATC. This value overwrites the PROXY value provided when the Listener is configured. This parameter is required.

### Configuring the Adapter on z/OS

#### How to:

- Declare Connection Attributes on z/OS
- Declare Connection Attributes Manually on z/OS

#### Reference:
- Connection Attributes for NATURAL CICS Transaction on z/OS

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

#### Procedure: How to Declare Connection Attributes on z/OS

You can configure the adapter from either the Web Console or the Data Management Console.

1. **From the Web Console menu bar, click Adapters**
   or
   **from the Data Management Console, expand the Adapters folder.**
   The Adapters folder opens.

2. **Expand the Available folder, if it is not already expanded.**

3. **Expand the appropriate group folder and the specific adapter folder.** The group folder is described in the connection attributes reference.
4. Right click the adapter name/version and select Configure.
   The Add Adapter to Configuration pane opens.

5. Select a communications protocol: TCP/IP or EXCI and click Next.

6. Enter values for the parameters required by the adapter as described in the connection attributes reference.

7. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for NATURAL CICS Transaction on z/OS

The CICS Transaction for Natural adapter is under the Procedures group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Communication Protocol

Select one of the following: TCP/IP or EXCI. Subsequent options vary slightly depending on this selection.

This selection is reflected in the Communication field on the second configuration pane.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Host name

For TCP/IP, enter the name of the host machine.

Application ID

For EXCI, enter the application ID of the CICS region.

Port

For TCP/IP, enter the port number.

Mirror

Is the name of the mirror transaction. The default value is EXCI.
This value overwrites the value provided in the Listener mode.

Proxy

Enter the name of a proxy program in NATURAL CICS. The default value is AASNATC.
This value overwrites the PROXY parameter value provided when the Listener is configured.
Natural driver

Enter the name of the NATURAL nucleus in CICS. This value is NATURAL CICS-dependent.

Security

For EXCI, Trusted security is supported under the following conditions: the server must be running with security OPSYS and IRC (Inter Region Communications) must be active in the CICS region. The adapter then connects to the CICS region using the credentials of the operating system user impersonated by the server data access agent.

For TCP/IP, there are two methods by which a user can be authenticated when connecting to the Adapter for NATURAL CICS Transactions:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the adapter, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to CICS Transactions, at connection time, for authentication.

User

Is the user name by which you are known to the adapter. This field is only displayed when the security mode of the server is non-trusted.

Password

Is the password associated with the user name. This field is only displayed when the security mode of the server is non-trusted.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default. If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:** How to Declare Connection Attributes Manually on z/OS

Explicit. The user ID and password are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the server global profile, edasprof.prf, for all users:

```bash
ENGINE NATCICS SET CONNECTION_ATTRIBUTES [connection] [node_name]/userid,password: "parameters_list"
```
**Password passthru.** The user ID and password are explicitly specified for each connection and passed to CICS Transactions, at connection time, for authentication.

```sql
ENGINE NATCICS SET CONNECTION_ATTRIBUTES [connection] [node_name] /: "parameters_list"
```

**Trusted.** The adapter connects to an operating system login using the credentials of the operating system user impersonated by the server data access agent.

```sql
ENGINE NATCICS SET CONNECTION_ATTRIBUTES [connection] [node_name] /: "parameters_list"
```

where:

- **NATCICS**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  Is a logical name used to identify this particular set of connection attributes. In the Access File, it becomes the CONNECTION=connection_name value. See *Access File Attributes* on page 1552.

- **node_name**
  Is a name of the NODE definition in the ODIN configuration file.

- **userid**
  Is the primary authorization ID by which you are known to the Adapter for NATURAL CICS Transactions.

- **password**
  Is the password associated with the primary authorization ID.

- **parameters_list**
  The following parameters are supported (some required; some optional):
  - **application_ID** is the application ID of the CICS region. This parameter is optional.
  - **mirror_name** is the name of the mirror transaction. This value overwrites the MIRROR value provided when the Listener is configured. This parameter is optional.
  - **communication** is the communication protocol being used.
  - **natnuc_name** is the name of the NATURAL nucleus in CICS. This value is NATURAL CICS-dependent. This parameter is required.
  - **natproxy_name** is the name of proxy program in CICS. The default value is AASNATC. This value overwrites the PROXY value provided when the Listener is configured. This parameter is required.
Managing NATURAL CICS Transactions Metadata

Managing NATURAL CICS Transactions Metadata

In this section:
Creating Synonyms

When the server invokes a transaction or procedure, it needs to know how to build the request, what parameters to pass, and how to format an answer set from the response. For each transaction the server will execute, you must create a synonym that describes the layout of the request/response area.

Creating Synonyms

How to:
Create a Synonym

Example:
Generating a Synonym

Reference:
Synonym Creation Parameters for NATURAL CICS Transactions
Managing Synonyms
Access File Attributes

Synonyms define unique names (or aliases) for each transaction or procedure that is accessible from the server. Synonyms are useful because they hide the underlying transaction or procedure from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows the input parameters and the response layout to be moved while allowing client applications to continue functioning without modification. For example, moving a transaction or procedure from a test region to production. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

CREATE SYNONYM is based on Local, Parameters, and Global data areas retrieved from the NATURAL ADABAS system file. These areas describe input and output buffers processed by NATURAL programs. If the NATURAL program does not have parameters, or if there are no NATURAL data areas that describe buffers, the CREATE SYNONYM command creates only template Master and Access Files.
Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.
- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

Reference: Synonym Creation Parameters for NATURAL CICS Transactions

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

**Natural System/User file with program libraries:**

**Data base ID**

- The database ID.

**File number**

- A number that identifies the Natural System system file.
File password

If set, the password associated with the Natural system file.

Mask for library names

Natural library with Natural programs.

Enter a string for filtering library names, inserting the wildcard character (%) at the beginning and/or end of the string.

For example, enter ABC% to display libraries whose names begin with the letters ABC; %ABC to display libraries whose names end with the letters ABC; %ABC% to display libraries whose names contain the letters ABC at the beginning, middle, or end; or % to display all libraries.

Mask for program names

The mask for returning a list of program name from which to chose. Enter a string for filtering program names, inserting the wildcard character (%) at the beginning and/or end of the string.

Program names

Choose a program from the drop-down list.

No data area available

Check this box if your data is defined in either a local data area or a parameter data area. For more information, see the Software AG documention on data area.

Note: If you check this box, you are re-prompted for database, file and password information on the next Create Synonym pane.

Leave this box unchecked if you are not using defined data.

Natural System/User file with data area definitions:

Data base ID

The database ID.

File number

A number that identifies the Natural System user file.

File password

If set, the password associated with the Natural system file.

Mask for the library names

The mask for returning a list of libraries from which to chose the one containing local/global data areas that describe the program’s parameters.
**Mask for the Data Area names**

Enter the mask for returning a list of the data areas from which you will choose the data area defining the program’s parameters.

**Natural library**

Select a library from the drop-down list.

**Synonym name**

The name of the synonym. You can retain the current name or change it.

Changing a synonym name enables you to manage multiple synonym versions to reflect, for example, multiple environments, or synonyms with different application logic such as different sets of Master File DEFINE attributes.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**Input Data Area/Output Data Area**

Specifies which data areas are for input parameters and which are for output parameters. You can specify the same data area as the source of both the input and output parameters.
Example: Generating a Synonym

The following example includes a NATURAL program and local data areas, with corresponding metadata.

IWAYIVPD NATURAL program:

```
DEFINE DATA
LOCAL USING NATTSTI /* INPUT PARMS FOR THE PROGRAM
LOCAL USING NATTSTO /* OUTPUT RECORD STRUCTURE
LOCAL
  1 #FUNC-TYPE
  2 #FUNC-GT (A2) INIT<'GT'>

NATURAL Data Buffer Processing API

This topic describes the flow control and implemented functions and response codes for the NATURAL data buffer processing API.

Flow of control:

NATCICS Adapter -> Proxy transaction (AASNATC) -> CICS NATURAL nucleus -> NATURAL program <-> AASSUBC. (Note that in the illustration in Generating a Synonym on page 1547 IWAYIVPD is an example of an AASNATC proxy transaction.)

Communication with the Data Mover program requires the following control block:

1. #REQUEST-PARMS
2. #FUNCTION (A2) One of the following: GT, PT, LC, LI
3. #OFFSET (I2)
4. #LENGTH (I2) Length of data for GT or PT functions
5. #RESPONSE-CODE (I4)
The implemented functions are:

- **GT.** Get input data by the offset. Only on the first call #OFFSET must be set to 0. Data Mover program uses #OFFSET to keep the cursor position in the data buffer. The length of the requested data must be provided for each call in the #LENGTH parameter. It should match the length of the area provided to receive the input data. For example:

  ```
  1  #EMP-NUM1 (A8)
  1  #EMP-SALARY (A6)
  ................
  MOVE 'GT' TO #FUNCTION
  MOVE 8 TO #LENGTH
  MOVE 0 TO OFFSET
  CALL 'AASSUBC' #FUNCTION #EMP-NUM1
  MOVE 6 TO #LENGTH
  CALL 'AASSUBC' #FUNCTION #EMP-SALARY
  ```

- **PT.** Put output data by the offset. Only on the first call #OFFSET must be set to 0. Data Mover program uses #OFFSET to keep the cursor position in the data buffer. The length of the stored data must be provided for each call in the #LENGTH parameter. It should match the length of the area containing output data. For example:

  ```
  1  #EMP-NUM1 (A8) INIT <'12345678'>
  1  #EMP-SALARY (A6) INIT <' 65000'>
  ................
  MOVE 'PT' TO #FUNCTION
  MOVE 8 TO #LENGTH
  MOVE 0 TO OFFSET - FIRST CALL ONLY
  CALL 'AASSUBC' #FUNCTION #EMP-NUM1
  MOVE 6 TO #LENGTH
  CALL 'AASSUBC' #FUNCTION #EMP-SALARY
  ```

- **LI.** Get length of the input data. Updates the #LENGTH field with the total length of all input data. No other parameters are needed. For example:

  ```
  MOVE 'LI' TO #FUNCTION
  CALL 'AASSUBC' #FUNCTION
  ```

- **LC.** Get length of the COMMAREA used to send/receive data. Updates the #LENGTH field with the COMMAREA length. No other parameters are needed. For example:

  ```
  MOVE 'LC' TO #FUNCTION
  CALL 'AASSUBC' #FUNCTION
  ```

**Implemented response-codes:**

- 0 - operation completed successfully.
- 4 - end-of-data. Cursor positioned beyond the input buffer. Indicates end of input data.
Invoking a NATURAL CICS Transaction

8 - end-of-buff. Cursor position plus requested length for PT operation exceeds the COMMAREA length. Indicates COMMAREA overflow.

**Note:**
- Always use the first field of a group when calling Data Mover programs. Notice that all calls in the previous examples are made with #FUNCTION not #REQUEST-PARMS.
- All input parameters must be processed before making a PT call. Otherwise, data will be overwritten.

### Invoking a NATURAL CICS Transaction

**How to:**
- Invoke a NATURAL CICS Transaction Using EX
- Invoke a NATURAL CICS Transaction Using TABLE
- Invoke a NATURAL CICS Transaction Using SELECT

**Example:**
- Invoking the Natural Program IWAYIVPD Using EX
- Invoking the Natural Program IWAYIVPD Using TABLE
- Invoking the Natural Program IWAYIVPD Using SQL SELECT

To invoke a NATURAL CICS transaction, you issue a Data Manipulation Language (DML) request, also known as a TABLE command, an SQL SELECT statement, or an EX command. (DML is the WebFOCUS internal retrieval language.) For information about the Data Manipulation Language, see the *Stored Procedure Reference* manual.

**Syntax:**

**How to Invoke a NATURAL CICS Transaction Using EX**

EX `[app_name_space/]synonym 1=parm1_val,..., N=parmN_val`

EX `[app_name_space/]synonym parm1_name=parm1_val,... , parmN_name=parmN_val`

EX `[app_name_space/]synonym [, parm1_val [,...[ , parmN_val]]]`

**where:**

`app_name_space`

Is the apps directory name under which the synonyms are stored. This value is optional.
**synonym**

Is the user friendly name of a repository entry that represents the object to be executed in the vendor environment.

**parm_name**

Is the name of the parameter taken from the input metadata description.

\[
1=parm\textsubscript{1}\_val \\
N=parm\textsubscript{N}\_val \\
parm\textsubscript{1}\_name \\
parm\textsubscript{1}\_val \\
parm\textsubscript{N}\_val
\]

Are the parameter values that match the input metadata description.

**Note:**

- Consecutive commas denote missing parameters in the positional form of the request.
- Values containing special characters (\(<\text{equal}\) sign \(<\text{space}\) \(<\text{comma}\)> ) must be encapsulated in double or single quotation marks.

**Example:** **Invoking the Natural Program IWAYIVPD Using EX**

```
SET EXORDER=PGM/FEX
EX IWAYIVPD 11111111, 11211111
```

**Syntax:** **How to Invoke a NATURAL CICS Transaction Using TABLE**

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
.
.
.
END
```

where:

**synonym**

Is the synonym of the NATURAL CICS transaction you want to invoke.

**parameter**

Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.
If the transaction does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.

*  
  Indicates that you want to display all indicated parameters.

**IF/WHERE**  
Is used if you want to pass values to input parameters.

**in-parameter**  
Is the name of an input parameter to which you want to pass a value.

**value**  
Is the value you are passing to an input parameter.

**Example:**  **Invoking the Natural Program IWAYIVPD Using TABLE**

```sql
TABLE FILE IWAYIVPD
  PRINT PERSONNEL_ID NAME BIRTH SALARY
  IF PERSONNEL_ID_FROM EQ '11111111'
  IF PERSONNEL_ID_TO EQ '11211111'
  IF SALARY NE 0
END
```

**Syntax:**  **How to Invoke a NATURAL CICS Transaction Using SELECT**

```sql
SQL
SELECT [parameter [,parameter] ... | *] FROM synonym
  [WHERE in-parameter = value]
  .
  .
END
```

**where:**

**synonym**  
Is the synonym of the NATURAL CICS transaction you want to invoke.

**parameter**  
Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.
If the transaction does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.

* Indicates that you want to display all indicated parameters.

WHERE Is used if you want to pass values to input parameters.
You must specify the value of each parameter on a separate line.

* * * * * *

Invoking the Natural Program IWAYIVPD Using SQL SELECT

Example: Invoking the Natural Program IWAYIVPD Using SQL SELECT

SQL
SELECT PERSONNEL_ID, NAME, BIRTH, SALARY
FROM IWAYIVPD
WHERE PERSONNEL_ID_FROM = '11111111' AND
     PERSONNEL_ID_TO = '11211111' AND
     SALARY != 0;
END
Invoking a NATURAL CICS Transaction
Using the Adapter for Netezza

The Adapter for Netezza allows applications to access specific Netezza data sources. The adapter converts application requests into Netezza calls and returns optimized answer sets to the requesting application.

Two implementations are available: ODBC and JDBC.

Topics:
- Preparing the Netezza Environment
- Configuring the Adapter for Netezza
- Managing Netezza Metadata
- Customizing the Netezza Environment
- Optimization Settings
Preparing the Netezza Environment

How to: Set Up the Environment on Windows and UNIX (JDBC)

Requirements for preparing the Netezza environment vary depending upon whether you intend to use an ODBC or a JDBC implementation.

- **For ODBC**, in order to use the Adapter for Netezza, you must install the Microsoft 32-bit Netezza Driver Manager on the Windows system. The Adapter for Netezza accesses all Netezza drivers installed and defined in the 32-bit Netezza Driver Manager.

- **For JDBC**, in order to use the Adapter for Netezza, you must install the Netezza driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running. For details, see *How to Set Up the Environment on Windows and UNIX (JDBC)* on page 1560.

Procedure: How to Set Up the Environment on Windows and UNIX (JDBC)

1. Identify the location of the Netezza Driver files by adding them to the environment variable CLASSPATH before server startup.
   
   For example, to set a UNIX or IBM i location for Netezza JDBC Driver files:

   ```
   CLASSPATH=/rdbms/netezza_jar/netezza-jdbc.jar:
   /rdbms/netezza_jar/bcprov-jdk14-122.jar:$CLASSPATH
   export CLASSPATH
   ```

   Similarly, on Windows, you would issue the command:

   ```
   set CLASSPATH=c:\usr\driver_files\<netezza_jdbc_driver_files>;%CLASSPATH%
   ```

   See the Netezza documentation for specific file names and their locations.

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.
   
   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace
   
   `edastart -show`
and check the special services section displays "JSCOM3 active".

If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server’s EDAPRINT. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the Server Installation manual.

**Configuring the Adapter for Netezza**

**In this section:**
- Declaring Connection Attributes
- Overriding the Default Connection
- Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

You can configure the adapter for an ODBC-based or a JDBC-based implementation. ODBC is preferred.

**Declaring Connection Attributes**

**How to:**
- Declare Connection Attributes
- Declare Connection Attributes Manually (ODBC)
- Declare Connection Attributes Manually (JDBC)

**Example:**
- Declaring Connection Attributes (ODBC)
- Declaring Connection Attributes (JDBC)

**Reference:**
- Connection Attributes for Netezza ODBC
- Updating the Connection String (ODBC)
- Connection Attributes for Netezza JDBC

In order to connect to a Netezza data source, the adapter requires connection and authentication information.
You supply this information using the \texttt{SET CONNECTION_ATTRIBUTES} command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (\textit{user.prf}), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (\textit{user.prf}), or in a group profile (if supported on your platform).

You can declare connections to more than one Netezza data source using the \texttt{SET CONNECTION_ATTRIBUTES} commands. The actual connection takes place when the first query is issued. If you issue multiple \texttt{SET CONNECTION_ATTRIBUTES} commands:

- The connection named in the \textit{first} \texttt{SET CONNECTION_ATTRIBUTES} command serves as the default connection.

- If more than one \texttt{SET CONNECTION_ATTRIBUTES} command contains the same connection name, the adapter uses the attributes specified in the \textit{last} \texttt{SET CONNECTION_ATTRIBUTES} command.

\textbf{Procedure: How to Declare Connection Attributes}

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click \textit{Adapters} or from the Data Management Console, expand the \textit{Adapters} folder.

   The Adapters folder opens.

2. Expand the \textit{Available} folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name/version and select \textit{Configure}.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter as described in the connection attributes reference.

   - \textit{Connection Attributes for Netezza ODBC} on page 1563.
   - \textit{Connection Attributes for Netezza JDBC} on page 1565.
6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

**Reference:** Connection Attributes for Netezza ODBC

The Netezza adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**Datasource**

The data source name (DSN). There is no default data source name. You must enter a value.

**Security**

There are two methods by which a user can be authenticated when connecting to an ODBC data source:

- **Explicit.** The user ID and password are explicitly specified for each connection pass to the ODBC data source, at connection time, for authentication.

- **Trusted.** The adapter connects to the ODBC data source as a Windows login using the credentials of the operating system user impersonated by the server data access agent.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).
**Syntax:**

**How to Declare Connection Attributes Manually (ODBC)**

**Explicit authentication.** The user ID and password are explicitly specified for each connection and passed to ODBC, at connection time, for authentication.

```
ENGINE SQLNEZ SET CONNECTION_ATTRIBUTES connection DSN_name/userid,password
```

**Trusted authentication.** The adapter connects to ODBC as a Windows login using the credentials of the Windows user impersonated by the server data access agent.

```
ENGINE SQLNEZ SET CONNECTION_ATTRIBUTES connection DSN_name/,
```

where:

- **SQLNEZ**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  - Is the logical name used to identify this particular set of connection attributes.
  
  Note that one blank space is required between `connection` and `DSN_name`.

- **DSN_name**
  - Is the Netezza Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

- **userid**
  - Is the primary authorization ID by which you are known to Netezza.

- **password**
  - Is the password associated with the primary authorization ID.

**Example:**

**Declaring Connection Attributes (ODBC)**

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the Netezza DSN named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE SQLNEZ SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS
```

**Reference:**

**Updating the Connection String (ODBC)**

The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.
The Web Console’s Migrate option migrates your server settings to the newer release. To access this option, select Workspace, then Configuration/Monitor from the menu bar. Right-click Migrate from the Server folder in the navigation pane, and select Configure. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the Migrate button. This is the recommended approach.

If you choose not to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=value.

For example, suppose that prior 7.6.1 the connection was defined as:

```sql
ENGINE SQLNEZ SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
```

When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

```sql
CONNECTION=DSN_A
```

If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

```sql
ENGINE SQLNEZ SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
```

**Reference:** Connection Attributes for Netezza JDBC

The Netezza adapter is under the SQL group folder.

This chart describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection name</td>
<td>Name to be used as a reference to the connection.</td>
</tr>
<tr>
<td>URL</td>
<td>Location URL for the Netezza data source.</td>
</tr>
</tbody>
</table>
### Syntax: How to Declare Connection Attributes Manually (JDBC)

```sql
ENGINE SQLNEZ SET CONNECTION_ATTRIBUTES connection 'URL'/userid,password
```

Where:

- **SQLNEZ**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  - Is the connection name.

- **URL**
  - Is the URL to the location of the Netezza data source.

- **userid**
  - Is the primary authorization ID by which you are known to the target database.

- **password**
  - Is the password associated with the primary authorization ID.
Example: Declaring Connection Attributes (JDBC)

The following SET CONNECTION_ATTRIBUTES command connects to data source using the Netezza Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

ENGINE SQLNEZ SET CONNECTION_ATTRIBUTES CON1 'jdbc:xxxxxxx://hostname:port/datasource

Overriding the Default Connection

How to:
Change the Default Connection

Example:
Selecting the Default Connection (ODBC)
Selecting the Default Connection (JDBC)

If multiple connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

ENGINE SQLNEZ SET DEFAULT_CONNECTION connection

where:

SQLNEZ
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

FOC1671, Command out of sequence

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  FOC1671, Command out of sequence.
Example: Selecting the Default Connection (ODBC)

The following SET DEFAULT_CONNECTION command selects the Netezza database server named SAMPLENAME as the default Netezza database server:

ENGINE SQLNEZ SET DEFAULT_CONNECTION SAMPLENAME

Example: Selecting the Default Connection (JDBC)

The following SET DEFAULT_CONNECTION command selects CON1 as the default connection.

ENGINE SQLNEZ SET DEFAULT_CONNECTION CON1

Controlling the Connection Scope

How to:

Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

ENGINE SQLNEZ SET AUTODISCONNECT ON {FIN|COMMIT}

where:

SQLNEZ

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN

For ODBC implementation only, disconnects automatically only after the session has been terminated. If connection scope is not set then FIN is the default behavior.

COMMIT

For ODBC implementation only, disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing Netezza Metadata

In this section:
Identifying the Adapter
Accessing Database Tables
Creating Synonyms
Data Type Support
Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

How to:
Identify the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLNEZ to identify the Adapter for Netezza.

Syntax: How to Identify the Adapter

FILE[NAME]=file, SUFFIX=SQLNEZ [,,$]

where:

file
Is the file name for the Master File. The file name without the .mas extension can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLNEZ
Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using Netezza, you must locally install the RDBMS Netezza Driver.
The Server can access third-party database tables across the JDBC network. You must specify a URL for the data source and, possibly, a user ID and/or password for the database you are accessing. You can define these parameters in either the server global profile or in a user profile.

Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Sample Generated Synonym

**Reference:**
Synonym Creation Parameters for Netezza
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

**Note:** If you are creating a synonym for a Netezza data source, you must first add the syntax `SET SYNONYM=BASIC` to the edasprof.prf file.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:**  **Synonym Creation Parameters for Netezza**

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Location of External SQL Scripts**

If you specify External SQL Scripts in the **Restrict Object type to** field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the **Base Location** field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the **Document Name** field, enter the file name with or without wild card characters.

- In the **Document Extension** field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the **Base Location** field, enter:

  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE

  The **Document Extension** is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the **Cardinality** check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
With foreign key

Select the With foreign key check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

Dynamic columns

To specify that the Master File created for the synonym should not contain column information, select the Dynamic columns check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

For Subquery

Only available when External SQL Scripts is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Data Type Support on page 1577.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.
**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Owner/Schema**

The user account that created the object or a collection of objects owned by a user.

**Type**

The object type (Table, View, and so on).

**Select tables**

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the **Select All** button.
- To select specific tables, select the corresponding check boxes.

**Example:**  **Sample Generated Synonym**

An Adapter for Netezza synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

**Master File nf29004.mas**

```
FILE=DIVISION, SUFFIX=SQLNEZ ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$
```

**Access File nf29004.acx**

```
SEGNAME=SEG1_4, TABLENAME=EDAQA.NF29004, CONNECTION=CON1, KEYS=1, WRITE=YES,$
```

**Reference:**  **Access File Keywords**

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td><strong>Keyword</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| **TABLENAME** | Identifies the Netezza table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows:  
TABLENAME=[owner.]table |
| **CONNECTION** | Indicates a previously declared connection. The syntax is:  
CONNECTION=connection  
CONNECTION=' ' indicates access to the local data source.  
Absence of the CONNECTION attribute indicates access to the default database server. |
| **KEYS** | Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first n fields in the Master File segment. |
| **WRITE** | Specifies whether write operations are allowed against the table. |
| **KEYFLD** **IXFLD** | Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.  
- KEYFLD is the FIELDNAME of the common column from the parent table.  
- IXFLD is the FIELDNAME of the common column from the related table.  
KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.  
**Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently. |
**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
### Data Management

Followed by these options, if applicable:

- **Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)

- **Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted.

- **Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values.

- **Reorganize.** Recreates the data source table preserving original data.

**Note:** This option is not available in the Web Console.

### Impact Analysis

Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS* manual for details about Impact Analysis reports.

### Copy

Copies the synonym to the clipboard.

### Delete

Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.

### Cut

Deletes the synonym and places it on the clipboard.

### Properties

Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

### Data Type Support

**Reference:**

Netezza Data Type Support

Data types are specific to the underlying data source.
**Reference: Netezza Data Type Support**

The following table lists adapter support for Netezza data types.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Alias</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>bigint</td>
<td>int8</td>
<td>read/write</td>
</tr>
<tr>
<td>boolean</td>
<td>bool</td>
<td>read/write</td>

<tr>
<td>byteint</td>
<td>int1</td>
<td>read/write</td>
</tr>
<tr>
<td>character $n$</td>
<td>char $n$</td>
<td>read/write</td>
</tr>
<tr>
<td>character varying $n$</td>
<td>varchar $n$</td>
<td>read/write</td>
</tr>
<tr>
<td>date</td>
<td></td>
<td>read/write</td>
</tr>
<tr>
<td>double precision</td>
<td>float8</td>
<td>read/write</td>
</tr>
<tr>
<td>integer</td>
<td>int, int4</td>
<td>read/write</td>
</tr>
<tr>
<td>interval $p$</td>
<td></td>
<td>uncertified</td>
</tr>
<tr>
<td>numeric $[p, s]$</td>
<td>decimal $p$, $s$</td>
<td>read/write</td>
</tr>
<tr>
<td>float $p$</td>
<td></td>
<td>read/write</td>
</tr>
<tr>
<td>real</td>
<td>float4</td>
<td>read/write</td>
</tr>
<tr>
<td>smallint</td>
<td>int2</td>
<td>read/write</td>
</tr>
<tr>
<td>time $p$ (Without time zone)</td>
<td></td>
<td>read/write</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note that subseconds are not displayed.</td>
</tr>
<tr>
<td>time $p$ (With time zone)</td>
<td>timetz</td>
<td>unsupported</td>
</tr>
<tr>
<td>timestamp $p$ (Without time zone)</td>
<td></td>
<td>read/write</td>
</tr>
</tbody>
</table>
Changing the Precision and Scale of Numeric Columns

How to:
Override the Default Precision and Scale

Example:
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

Syntax: How to Override the Default Precision and Scale

ENGINE SQLNEZ SET CONVERSION RESET
ENGINE SQLNEZ SET CONVERSION format RESET
ENGINE SQLNEZ SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLNEZ SET CONVERSION format [PRECISION MAX]

where:

SQLNEZ

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

RESET

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

format

Is any valid format supported by the data source. Possible values are:

INTEGER which indicates that the command applies only to INTEGER columns.

DECIMAL which indicates that the command applies only to DECIMAL columns.

REAL which indicates that the command applies only to single-precision floating-point columns.

Note: Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
Example: Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```sql
ENGINE SQLNEZ SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```sql
ENGINE SQLNEZ SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```sql
ENGINE SQLNEZ SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```sql
ENGINE SQLNEZ SET CONVERSION RESET
```

Customizing the Netezza Environment

In this section:

- Specifying a Timeout Limit
- Cancelling Long Requests (JDBC)
- Obtaining the Number of Rows Updated or Deleted
- Specifying the Transaction Isolation Level (ODBC)

The Adapter for Netezza provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

How to:

Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to Netezza.

Syntax: How to Issue the TIMEOUT Command

```sql
ENGINE SQLNEZ SET TIMEOUT {nn|0}
```
where:

- **SQLNEZ**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **nn**
  - Is the number of seconds before a time-out occurs. 30 is the default value.

- **0**
  - Represents an infinite period to wait for a response.

### Cancelling Long Requests (JDBC)

**How to:**
Cancel Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

**Procedure: How to Cancel Long Requests**

1. From the Web Console menu bar choose **Workspace, Configuration/Monitor, Java Services, DEFAULT**. Right-click on **DEFAULT** and select **Agents**.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select **Stop**.

### Obtaining the Number of Rows Updated or Deleted

**How to:**
Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking **Data Adapters** on the menu bar, clicking a configured adapter, and choosing **Change Settings** from the menu. The Change Settings pane opens.
Syntax: How to Obtain the Number of Rows Updated or Deleted

ENGINE SQLNEZ SET PASSRECS {ON|OFF}

where:

SQLNEZ

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Specifying the Transaction Isolation Level (ODBC)

Syntax: How to Specify Transaction Isolation Level From a SET Command

You can specify transaction isolation level by issuing the following command

ENGINE SQLNEZ SET ISOLATION {RU|RC|RR|SE}

where:

RU

Sets the transaction isolation level to Read Uncommitted.

RC

Sets the transaction isolation level to Read Committed.

RR

Sets the transaction isolation level to Repeatable Read.
Sets the transaction isolation level to Serializable Read.

Optimization Settings

In this section:
- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

Optimizing Requests

How to:
- Optimize Requests

Example:
- SQL Requests Passed to the RDBMS With Optimization OFF
- SQL Requests Passed to the RDBMS With Optimization ON

Reference:
- SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

```
SQL SQLNEZ SET {OPTIMIZATION|SQLJOIN} setting
```

where:

```
SQLNEZ
```

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.
**SQLJOIN**

Is a synonym for OPTIMIZATION.

**setting**

Is the optimization setting. Valid values are as follows:

- **ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

- **OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.

Both OPTIMIZATION settings produce the same report.

**Example: SQL Requests Passed to the RDBMS With Optimization OFF**

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLNEZ SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
   SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
   IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
FOR FETCH ONLY;
```
Example:  SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLNEZ SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
  FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
  WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
  GROUP BY T2.EID, T1.LN
  ORDER BY T2.EID, T1.LN;
```

Reference:  SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

How to:
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

Example:
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

Reference:
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.
Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:** How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```
SQL SQLNEZ SET OPTIFTHENELSE {ON | OFF}
```

where:

**SQLNEZ**

Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Enables IF-THEN-ELSE optimization. This is the default.

**OFF**

Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```
SQL SQLNEZ SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME WHERE DEF1 EQ 1
END
```
The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' ')) AND (T1.'DPT' = 'MIS'))));
```

**Example: Using IF-THEN_ELSE Optimization With Aggregation**

Consider the following request:

```sql
SQL SQLNEZ SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

**Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False**

```sql
SQL SQLNEZ SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END
```
Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```

**Reference: SQL Limitations on Optimization of DEFINE Expressions**

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  ```
  X = X + 1;
  ```
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX and MIN prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

**Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Optimization Settings
The Adapter for Nucleus allows applications to access Nucleus data sources. The adapter converts application requests into native Nucleus statements and returns optimized answer sets to the requesting application.

**Topics:**
- Preparing the Nucleus Environment
- Configuring the Adapter for Nucleus
- Managing Nucleus Metadata
- Customizing the Nucleus Environment
- Optimization Settings
Preparing the Nucleus Environment

**How to:**

Set Up the Environment on Windows
Set Up the Environment on UNIX

In order to use the Adapter for Nucleus, the Nucleus database and ODBC must be installed and configured and the path to the Nucleus ODBC libraries directory must be added to SYSTEM LIBRARY PATH. See the SandTechnology Nucleus(r) documentation for more information about requirements for ODBC installation and configuration.

**Procedure: How to Set Up the Environment on Windows**

On Windows, the Nucleus environment is set up during the installation of Nucleus.

**Procedure: How to Set Up the Environment on UNIX**

You can access Nucleus using the NUCINI environment variable and one of the following:

- $HOME/.odbc.ini file
- ODBCINI environment variable.

Point the NUCINI variable to the directory where SandTechnology ODBC(r) is installed. For example:

```
NUCINI=/usr/nucleus/odbc
export NUCINI
```

The ODBCINI variable holds the absolute path to the *.ini file, which describes the Nucleus data sources. For example:

```
ODBCINI=/usr/ibiuser/odbc/nucodbc.ini
export ODBCINI
```
Configuring the Adapter for Nucleus

In this section:
Declaring Connection Attributes
Overriding the Default Connection
Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Example:
Declaring Connection Attributes

Reference:
Connection Attributes for Nucleus
Updating the Connection String

In order to connect to a Nucleus database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).
You can declare connections to more than one Nucleus database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the Nucleus Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**.
   - or
   - From the Data Management Console, expand the **Adapters** folder.
     The Adapters folder opens.

2. Expand the **Available** folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select **Configure**.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click **Configure**. The configured adapter is added to the Adapters list in the navigation pane.

**Reference: Connection Attributes for Nucleus**

The Nucleus adapter is under the **SQL** group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the **Configure** button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.
Datasource

The data source name (DSN). There is no default data source name. You must enter a value.

User

Authorization ID to connect to the source.

Password

Password associated with the authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```sql
ENGINE SQLNUC SET CONNECTION_ATTRIBUTES connection
DSN_name/userid,password
```

where:

SQLNUC

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between connection and DSN_name.

DSN_name

Is the Nucleus Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

userid

Is the primary authorization ID by which you are known to Nucleus.
password

Is the password associated with the primary authorization ID.

**Example: Declaring Connection Attributes**

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the Nucleus DSN named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```sql
ENGINE SQLNUC SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS
```

**Reference: Updating the Connection String**

The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Web Console’s Migrate option migrates your server settings to the newer release. To access this option, select Workspace, then Configuration/Monitor from the menu bar. Right-click Migrate from the Server folder in the navigation pane, and select Configure. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the Migrate button. This is the recommended approach.

If you choose not to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=value.

For example, suppose that prior 7.6.1 the connection was defined as:

```sql
ENGINE SQLNUC SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
```

When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

```text
CONNECTION=DSN_A
```
If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

```
ENGINE SQLNUC SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
```

### Overriding the Default Connection

**How to:**

Change the Default Connection

**Example:**

Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:**

**How to Change the Default Connection**

```
ENGINE SQLNUC SET DEFAULT_CONNECTION connection
```

where:

- **SQLNUC**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  
  Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

```
FOC1671, Command out of sequence.
```
**Example:** **Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```
ENGINE SQLNUC SET DEFAULT_CONNECTION SAMPLENAME
```

**Controlling the Connection Scope**

### How to: Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:** **How to Control the Connection Scope**

```
ENGINE SQLNUC SET AUTODISCONNECT ON {FIN | COMMAND | COMMIT}
```

where:

- **SQLNUC**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **FIN**
  - Disconnects automatically only after the session has been terminated. FIN is the default value.

- **COMMAND**
  - Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

- **COMMIT**
  - Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing Nucleus Metadata

When the server accesses a data source, it needs to know how to interpret the data that it finds. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Nucleus data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each Nucleus table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source's location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server's metadata.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.
1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**
- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.
- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

**Reference:** Synonym Creation Parameters for Nucleus

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (",";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.
Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify **External SQL Scripts** in the **Restrict Object type to** field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the **Base Location** field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the **Document Name** field, enter the file name with or without wild card characters.

- In the **Document Extension** field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the **Base Location** field, enter:

  ```sql
  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
  ```

- The **Document Extension** is understood to be MBR. You can enter this value explicitly or leave the input box blank.
During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.
Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Nucleus Data Type Support on page 1606.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

☐ To select all tables in the list, click the Select All button.
☐ To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Nucleus synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

FILE=DIVISION, SUFFIX=SQLNUC ,$
SENAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON ,$

Generated Access File nf29004.acx

SENAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=DSN_A,KEYS=1,WRITE=YES,
**Reference: Access File Keywords**

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the Nucleus table. The value assigned to this attribute can</td>
</tr>
<tr>
<td></td>
<td>include the name of the owner (also known as schema) as follows:</td>
</tr>
<tr>
<td></td>
<td>TABLENAME=[owner.] table</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is:</td>
</tr>
<tr>
<td></td>
<td>CONNECTION=connection</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table.</td>
</tr>
<tr>
<td></td>
<td>Range is 0 to 64. Corresponds to the first ( n ) fields in the Master File</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
</tbody>
</table>

**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface.</td>

<td>TIME</td>
<td>HHIS</td>
<td>HHIS</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>HYYMDm</td>
<td>HYYMDm</td>
</tr>
<tr>
<td><strong>Numeric Data Types</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SMALLINT</td>
<td>I6</td>
<td>I4</td>
</tr>
<tr>
<td>INTEGER</td>
<td>I11</td>
<td>I4</td>
</tr>
<tr>
<td>NUMERIC, DECIMAL (p,s)</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td>FLOAT</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td>REAL</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td><strong>LOB Data Types</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BLOB</td>
<td>BLOB</td>
<td>BLOB</td>
</tr>
</tbody>
</table>
The following table lists how the server maps Character data types. This mapping can be changed based on the value of LONGCHAR. The default value is ALPHA.

<table>
<thead>
<tr>
<th>Nucleus Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>USAGE</td>
<td>ACTUAL</td>
</tr>
<tr>
<td>CHAR (n)</td>
<td>n is an integer between 1 and 256.</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td></td>
<td>n is an integer between 257 and 4056.</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>n is an integer between 1 and 256.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td></td>
<td>n is an integer between 257 and 4056.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
</tbody>
</table>

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.

### Trailing Blanks in SQL Expressions

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

```
ENGINE SQLNUC SET TRIM_LITERALS ON
```

is available to ensure backward compatibility.
Changing the Precision and Scale of Numeric Columns

**How to:**

Override the Default Precision and Scale

**Example:**

Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

ENGINE SQLNUC SET CONVERSION RESET
ENGINE SQLNUC SET CONVERSION format RESET
ENGINE SQLNUC SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLNUC SET CONVERSION format [PRECISION MAX]

where:

**SQLNUC**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**

Is any valid format supported by the data source. Possible values are:

**INTEGER** which indicates that the command applies only to INTEGER columns.

**DECIMAL** which indicates that the command applies only to DECIMAL columns.

**REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
FLOAT which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
Example: Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

ENGINE SQLNUC SET CONVERSION INTEGER PRECISION 7

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

ENGINE SQLNUC SET CONVERSION FLOAT PRECISION 14 3

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

ENGINE SQLNUC SET CONVERSION INTEGER RESET

The following example shows how to set the precision and scale attributes for all fields to the defaults:

ENGINE SQLNUC SET CONVERSION RESET

Customizing the Nucleus Environment

In this section:

Obtaining the Number of Rows Updated or Deleted

The Adapter for Nucleus provides several parameters for customizing the environment and optimizing performance.

Obtaining the Number of Rows Updated or Deleted

How to:

Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

ENGINE SQLNUC SET PASSRECS {ON|OFF}
where:

**SQLNUC**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**
Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

**OFF**
Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

### Optimization Settings

**In this section:**
- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

### Optimizing Requests

**How to:**
Optimize Requests

**Example:**
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

**Reference:**
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.
Optimization Settings

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax:** How to Optimize Requests

```
SQL SQLNUC SET {OPTIMIZATION|SQLJOIN} setting
```

where:

**SQLNUC**

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**SQLJOIN**

Is a synonym for OPTIMIZATION.

**setting**

Is the optimization setting. Valid values are as follows:

- **ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

- **OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.

Both OPTIMIZATION settings produce the same report.

**Example:** SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SLAGGR and STMTRACE allocated.
When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLNUC SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
FOR FETCH ONLY;
```

**Example:** **SQL Requests Passed to the RDBMS With Optimization ON**

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLNUC SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
SELECT T2.EID,T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID,T1.LN
ORDER BY T2.EID,T1.LN;
```
Reference: SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

How to:
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

Example:
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

Reference:
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

SQL SQLNUC SET OPTIFTHENELSE {ON | OFF}

where:

SQLNUC

Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.
ON
    Enables IF-THEN-ELSE optimization. This is the default.
OFF
    Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
SQL SQLNUC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN',T1.'FN',T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' '))
       AND (T1.'DPT' = 'MIS'))));
```

**Example:** Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
SQL SQLNUC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2 ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END
```

Adapter Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS
The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1."LN") FROM USER1.'EMPINFO' T1
    WHERE (((T1."LN" = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1."LN") FROM USER1.'EMPINFO' T1
    WHERE (((NOT (T1."LN" = 'SMITH'))) AND (T1."LN" = 'JONES'));
```

**Example:** Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```sql
SQL SQLNUC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END
```

```sql
TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END
```

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1."FN" FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```

**Reference:** SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  ```sql
  X=X+1;
  ```
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.
  **Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.

- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.

- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).
  **Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Using the Adapter for ODBC

The Adapter for ODBC allows applications to access ODBC data sources. The adapter converts application requests into native ODBC statements and returns optimized answer sets to the requesting application.

For details about ODBC-supported data sources, see the Server Release Notes.

Topics:
- Preparing the ODBC Environment
- Configuring the Adapter for ODBC
- Managing ODBC Metadata
- Customizing the ODBC Environment
- Optimization Settings
Preparing the ODBC Environment

In order to use the Adapter for ODBC, you must install the Microsoft 32-bit ODBC Driver Manager on the Windows system. The Adapter for ODBC accesses all ODBC drivers installed and defined in the 32-bit ODBC Driver Manager.

**Note:**

- If Information Builders offers an adapter for a specific data source type, you should use that adapter to access that type. The Adapter for ODBC does not support data source types for which a specific adapter already exists. For example, Information Builders provides the Adapter for DB2 to access DB2 databases, so you should not use the Adapter for ODBC to access DB2.

- If Information Builders does not currently offer a specific adapter for a data source type, you may use the Adapter for ODBC with a vendor-provided ODBC driver. Note that the adapter conforms to generic ODBC standards. Vendors, on the other hand, may have interpreted or extended those standards for their specific data source requirements. If this introduces an incompatibility, you may experience inconsistent behavior when using the adapter for that vendor’s data source type. If this occurs please contact Customer Support Services for assistance. Information Builders will work with your enterprise to try and support your data access needs.

Configuring the Adapter for ODBC

**In this section:**

Declaring Connection Attributes

Overriding the Default Connection

Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Declaring Connection Attributes

**How to:**
Declaring Connection Attributes
Declaring Connection Attributes Manually

**Example:**
Declaring Connection Attributes

**Reference:**
Connection Attributes for ODBC
Updating the Connection String

In order to connect to the ODBC database server, the adapter requires connection and authentication information. You supply this information using the `SET CONNECTION_ATTRIBUTES` command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one ODBC database server by including multiple `SET CONNECTION_ATTRIBUTES` commands. The actual connection to the ODBC Server takes place when the first query that references the connection is issued. If you issue multiple `SET CONNECTION_ATTRIBUTES` commands:

- The connection named in the first `SET CONNECTION_ATTRIBUTES` command serves as the default connection.

- If more than one `SET CONNECTION_ATTRIBUTES` command contains the same connection name, the adapter uses the attributes specified in the last `SET CONNECTION_ATTRIBUTES` command.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click `Adapters`. 

Configuring the Adapter for ODBC

or

From the Data Management Console, expand the Adapters folder.
The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for ODBC

The ODBC adapter is under the SQL group folder.
The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Connection name
Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource
The data source name (DSN). There is no default data source name. You must enter a value.
If a File DSN is used this must be the name of the file (for example, samplefdsn.dsn.)

Security
There are two methods by which a use can be authenticated when connecting to an ODBC data source:

- Explicit. The user ID and password are explicitly specified for each connection pass to the ODBC data source, at connection time, for authentication.

- Trusted. The adapter connects to the ODBC data source as a Windows login using the credentials of the operating system user impersonated by the server data access agent.
User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

File DSN parameters (optional)

The path to the ODBC File DSN that is defined on your Windows machine or network.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

Explicit authentication. The user ID and password are explicitly specified for each connection and passed to ODBC, at connection time, for authentication.

For User/System DSN:

ENGINE SQLODBC SET CONNECTION_ATTRIBUTES connection DSN_name/userid,password

For File DSN:

ENGINE SQLODBC SET CONNECTION_ATTRIBUTES connection
FileDSN_name/userid,password:'FileDSN_path;'

Trusted authentication. The adapter connects to ODBC as a Windows login using the credentials of the Windows user impersonated by the server data access agent.

For User/System DSN:

ENGINE SQLODBC SET CONNECTION_ATTRIBUTES connection DSN_name/,

For File DSN:

ENGINE SQLODBC SET CONNECTION_ATTRIBUTES connection
FileDSN_name/,:'filedsn=FileDSN_path;','
where:

**SQLODBC**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**
Is the logical name used to identify this particular set of connection attributes.
Note that one blank space is required between connection and DSN_name.

**DSN_name**
Is the ODBC Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

**FileDSN_name**
Is the name of ODBC File Data Source Name (DSN) you wish to access.

**userid**
Is the primary authorization ID by which you are known to ODBC.

**password**
Is the password associated with the primary authorization ID.

**FileDSN_path**
Is the path to the ODBC File DSN, which may reside on the hard drive or on the network.

**Example: Declaring Connection Attributes**

For User/System DSN:

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the ODBC DSN named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE SQLODBC SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS
```

For File DSN:

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 via the ODBC File DSN named SAMPLESERVER.dsn with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE SQLODBC SET CONNECTION_ATTRIBUTES CON2
SAMPLESERVER.dsn /R729999B,1525B6F3331C2FB3:'filedsn=C:\ SAMPLESERVER.dsn;'
```
Reference: Updating the Connection String

The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Web Console Migrate option migrates your server settings to the newer release. To access this option, select Workspace, then Configuration/Monitor from the menu bar. Right-click Migrate from the Server folder in the navigation pane, and select Configure. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the Migrate button. This is the recommended approach.

If you choose not to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=value.

For example, suppose that prior 7.6.1 the connection was defined as:

```sql
ENGINE SQLODBC SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
```

When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

```text
CONNECTION=DSN_A
```

If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

```sql
ENGINE SQLODBC SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
```
Overriding the Default Connection

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:**

**How to Change the Default Connection**

```
ENGINE SQLODBC SET DEFAULT_CONNECTION connection
```

where:

```
SQLODBC
```
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

```
connection
```
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```
  FOC1671, Command out of sequence.
  ```

**Example:**

**Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```
ENGINE SQLODBC SET DEFAULT_CONNECTION SAMPLENAME
```
Controlling the Connection Scope

How to:
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax:  
How to Control the Connection Scope

ENGINE SQLODBC SET AUTODISCONNECT ON {FIN | COMMAND | COMMIT}

where:

SQLODBC
- Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN
- Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMAND
- Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

COMMIT
- Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing ODBC Metadata

In this section:
- Identifying the Adapter
- Accessing Database Tables
- Creating Synonyms
- Data Type Support
- Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the ODBC data types.

Identifying the Adapter

**How to:**

Identify the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLODBC to identify the Adapter for ODBC.

**Syntax:**

**How to Identify the Adapter**

```
FILE[NAME]=file, SUFFIX=SQLODBC [,,$]
```

**where:**

- `file`
  - Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

- `SQLODBC`
  - Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using ODBC, you must locally install the RDBMS ODBC Driver.
The Server can access third-party database tables across the network ODBC. You must provide a system data source name and possibly a user ID and/or password for the database tables you are accessing. You can define these parameters in either the server global profile or in a user profile.

Creating Synonyms

How to:
Create a Synonym

Example:
Sample Generated Synonym

Reference:
Synonym Creation Parameters for ODBC
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each ODBC table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.
4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**
- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.
- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

**Reference: Synonym Creation Parameters for ODBC**

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

### Location of External SQL Scripts

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the **Base Location** field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the **Document Name** field, enter the file name with or without wildcard characters.
- In the **Document Extension** field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members.

The following entry illustrates this method:

- In the **Base Location** field, enter:

```
/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
```

- The **Document Extension** is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

### Cardinality

Select the **Cardinality** check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
**With foreign key**

Select the *With foreign key* check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Customize data type mappings**

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support* on page 1636.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Owner/Schema**

The user account that created the object or a collection of objects owned by a user.

**Type**

The object type (Table, View, and so on).

**Select tables**

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the **Select All** button.
- To select specific tables, select the corresponding check boxes.

**Example: Sample Generated Synonym**

An Adapter for ODBC synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

**Master File nf29004.mas**

FILE=DIVISION, SUFFIX=ODB ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF,$

**Access File nf29004.acx**

SEGNAME=SEG1_4, TABLENAME=EDAQA.NF29004,
CONNECTION=DB1, KEYS=1, WRITE=YES,$

**Reference: Access File Keywords**

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td><strong>Keyword</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| **TABLENAME** | Identifies the ODBC table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows:  
  \[ TABLENAME= [owner.] table \] |
| **CONNECTION** | Indicates a previously declared connection. The syntax is:  
  \[ CONNECTION=connection \]  
  \[ CONNECTION=' ' \] indicates access to the local ODBC database server.  
  Absence of the CONNECTION attribute indicates access to the default database server. |
| **DBSPACE** | Optional keyword that indicates the storage area for the table. For example:  
  \[ datasource.tablespace \]  
  \[ DATABASE . datasource \] |
| **KEYS** | Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first \( n \) fields in the Master File segment. |
| **WRITE** | Specifies whether write operations are allowed against the table. |
| **KEYFLD** | Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. |
| **IXFLD** | - KEYFLD is the FIELDNAME of the common column from the parent table.  
  - IXFLD is the FIELDNAME of the common column from the related table.  
  
  KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.  
  
  **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently. |
**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
Data Management

Followed by these options, if applicable:

**Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)

**Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted.

**Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values.

**Reorganize.** Recreates the data source table preserving original data.

**Note:** This option is not available in the Web Console.

Impact Analysis

Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS* manual for details about Impact Analysis reports.

Copy

Copies the synonym to the clipboard.

Delete

Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.

Cut

Deletes the synonym and places it on the clipboard.

Properties

Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

**Data Type Support**

Data types are specific to the underlying data source.

If you wish to use the Adapter for ODBC to access a data source, first check whether Information Builders already provides an adapter for that type. To find out which adapters are currently available, see *Supported Adapters* on page 66.
### Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

```sql
ENGINE SQLODBC SET CONVERSION RESET
ENGINE SQLODBC SET CONVERSION format RESET
ENGINE SQLODBC SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLODBC SET CONVERSION format [PRECISION MAX]
```

where:

- **SQLODBC**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **RESET**
  Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

- **format**
  Is any valid format supported by the data source. Possible values are:
  - **INTEGER** which indicates that the command applies only to INTEGER columns.
  - **DECIMAL** which indicates that the command applies only to DECIMAL columns.
  - **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```
ENGINE SQLODBC SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```
ENGINE SQLODBC SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```
ENGINE SQLODBC SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```
ENGINE SQLODBC SET CONVERSION RESET
```

Customizing the ODBC Environment

**In this section:**
- Specifying a Timeout Limit
- Obtaining the Number of Rows Updated or Deleted
- Specifying the Transaction Isolation Level

The Adapter for ODBC provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

**How to:**

Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to ODBC.

**Syntax:**

```
How to Issue the TIMEOUT Command
ENGINE SQLODBC SET TIMEOUT {nn | 0}
```
where:

SQLODBC
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn
  Is the number of seconds before a time-out occurs. 30 is the default value.

0
  Represents an infinite period to wait for a response.

**Obtaining the Number of Rows Updated or Deleted**

**How to:**

Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

**How to Obtain the Number of Rows Updated or Deleted**

ENGINE SQLODBC SET PASSRECS {ON|OFF}

where:

SQLODBC
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON
  Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF
  Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.
Specifying the Transaction Isolation Level

How to:
Specify Transaction Isolation Level From a SET Command

You can specify the transaction isolation level from the Web Console or using the SET ISOLATION command.

Syntax:  
How to Specify Transaction Isolation Level From a SET Command

You can specify transaction isolation level by issuing the following command

```
ENGINE SQLODBC SET ISOLATION {RU|RC|RR|SE}
```

where:

RU
Sets the transaction isolation level to Read Uncommitted.

RC
Sets the transaction isolation level to Read Committed.

RR
Sets the transaction isolation level to Repeatable Read.

SE
Sets the transaction isolation level to Serializable Read.

Optimization Settings

In this section:

Optimizing Requests
Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

**How to:**
Optimize Requests

**Example:**
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

**Reference:**
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax:**

```
SQL SQLODBC SET {OPTIMIZATION|SQLJOIN} setting
```

where:

- **SQLODBC**
  - Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

- **SQLJOIN**
  - Is a synonym for OPTIMIZATION.

- **setting**
  - Is the optimization setting. Valid values are as follows:
    - **ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.
    - **OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:**  **SQL Requests Passed to the RDBMS With Optimization OFF**

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```sql
SQL SQLODBC SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
FOR FETCH ONLY;
```

**Example:**  **SQL Requests Passed to the RDBMS With Optimization ON**

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```sql
SQL SQLODBC SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID, T1.LN
ORDER BY T2.EID, T1.LN;
```

**Reference: SQL Generation in Optimization Examples**

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:**
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
**Syntax:**

**How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields**

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

SQL SQLODBC SET OPTIFTHENELSE {ON|OFF}

where:

**SQLODBC**

Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Enables IF-THEN-ELSE optimization. This is the default.

**OFF**

Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:**

**Using IF-THEN_ELSE Optimization Without Aggregation**

Consider the following request:

```sql
SQL SQLODBC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ '  ')
    AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' '))
    AND (T1.'DPT' = 'MIS'))));
```
Example: Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
SQL SQLODBC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
   ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
   WHERE (((T1.'LN' = 'SMITH')));
```

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
   WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```sql
SQL SQLODBC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
Reference: SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  
  \[ X=X+1; \]

- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

  **Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.

- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.

- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

  **Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Optimization Settings
Using the Adapter for Oracle

The Adapter for Oracle allows applications to access Oracle data sources. The adapter converts data or application requests into native Oracle statements and returns optimized answer sets to the requesting program.

Topics:
- Preparing the Oracle Environment
- Configuring the Adapter for Oracle
- Managing Oracle Metadata
- Reporting Against an Oracle Stored Procedure
- Customizing the Oracle Environment
- Optimization Settings
- Calling an Oracle Stored Procedure Using SQL Passthru
Preparing the Oracle Environment

In this section:
- Connecting to a Remote Oracle Database Server
- XA Support
- Configuring Oracle for Unicode

How to:
- Prepare the Oracle Environment on Windows
- Prepare the Oracle Environment on UNIX
- Prepare the Oracle Environment on z/0S
- Prepare the Oracle Environment on OpenVMS

Example:
- Specifying the $ORACLE_SID on OpenVMS

The Adapter for Oracle minimally requires the installation of the Oracle Client. The Oracle Client allows you to connect to a local or remote Oracle database server.

Make sure that the client shared library, libclntsh, was generated on UNIX and z/0S USS.

If you are using Oracle 11g or 10g and wish to take advantage of the adapter's support for Unicode, see Configuring Oracle for Unicode on page 1653.

Procedure: How to Prepare the Oracle Environment on Windows

On Windows, the Oracle environment is set up during the installation of Oracle.

Procedure: How to Prepare the Oracle Environment on UNIX

You can issue the following export commands in the edastart file. (Alternatively, you can issue them in a separate shell file, a database profile, or a user profile.)

1. On the Web Console menu bar, select Workspace, then Configuration. In the Configuration pane, expand the Configuration Files folder and choose Server Startup Script to edit the edastart file. Place the export commands immediately following the shell setting. For example:

```
#!/bin/ksh
export ORACLE_SID=orac
export ORACLE_HOME=/usr/oracle/orac
...```

2. Specify the Oracle database instance to access using the UNIX environment variable $ORACLE_SID. For example:

```
ORACLE_SID=orac
export ORACLE_SID
```

3. Specify the location of the Oracle database you wish to access using the UNIX environment variable $ORACLE_HOME. For example, to set the home directory for the Oracle software to /usr/orac, specify:

```
ORACLE_HOME=/usr/oracle/orac
export ORACLE_HOME
```

4. Specify the path to the Oracle shared library using the appropriate platform-dependent UNIX environment variable, such as $LD_LIBRARY_PATH for Sun Sparc, $SHLIB_PATH for HP-UX, and $LIBPATH for AIX.

This must be done only for an unsecured server. For example:

```
LD_LIBRARY_PATH=$ORACLE_HOME/lib:$LD_LIBRARY_PATH
export LD_LIBRARY_PATH
```

**Note:** If the server is running with security on, the LD_LIBRARY_PATH variable is ignored. In this case, you must use IBI_LIBPATH.

---

**Procedure:** How to Prepare the Oracle Environment on z/OS

The configuration for Oracle on z/OS requires that EDASTART JCL is used to allocate Oracle specific variables. This can be done using the EDAENV ddname in the JCL:

```
ORACLE_SID=ORAT
ORACLE_HOME=/usr/lpp/orac
LIBPATH=$ORACLE_HOME/lib
```

If you are running a secure server, then your Oracle run-time load and message libraries must be APF-authorized in order to avoid the following error message:

**ORA-01019:** unable to allocate memory in the user side

Another option is to implement an internal security mechanism by placing the following parameter in EDASERVE DDNAME.

```
APFAUTH=INTERNAL
```

With this setting, the server calls Oracle in a non-authorized state so that Oracle libraries do not require any special APF authorization (except when the Oracle documentation states differently).
Preparing the Oracle Environment

Syntax: How to Prepare the Oracle Environment on OpenVMS

When a site creates an Oracle SID, the Oracle software automatically generates a DCL setup script so users and products such as the Reporting Server, can properly invoke the environment.

The specification for the location of the Oracle setup file is:

$@disk:[oracle_root.DB_oraclesiddb]ORAUSER_oraclesiddb.COM

where:

disk
  Is the disk on which Oracle is installed.

oracle_root
  Is the root directory of the Oracle installation.

oraclesiddb
  Is the name of the Oracle database. This name does not need to match the Oracle SID.

EDAENV.COM is an optional OpenVMS file that is invoked at server start up to issue DCL commands such as calls to DBMS setup files. Due to the use of symbols and job logicals in Oracle, the only proper way to invoke the Oracle setup file is by using the EDAENV.COM file.

By default, EDAENV.COM does not exist and must be manually created in the [.BIN] directory of EDACONF. In this case, and in its simplest form, EDAENV.COM will contain a single line of syntax that specifies the call to the Oracle setup file.

Example: Specifying the $ORACLE_SID on OpenVMS

$@3$DKB0: [ORACLE.DB_ORAC]ORAUSER_ORAC.COM

Connecting to a Remote Oracle Database Server

Using the standard rules for deploying the Oracle Client, the server supports connections to:

- Local Oracle database servers.

- Remote Oracle database servers. To connect to a remote Oracle database server, the Oracle tnsnames.ora file on the source machine must contain an entry pointing to the target machine and the listening process must be running on the target machine.

Once you are connected to an Oracle database server, that server may define Oracle DATABASE LINKs that can be used to access Oracle tables on other Oracle database servers.
**XA Support**

Read/write applications accessing Oracle data sources are able to perform transactions managed in XA-compliant mode.

To activate the XA Transaction Management feature, the server has to be configured in Transaction Coordination Mode, using the Web console configuration functions. Using Transaction Coordination Mode guarantees the integrity of data modification on all of the involved DBMSs and protects part of the data modifications from being committed on one DBMS and terminated on another.

For complete documentation on XA compliance, see *XA Support* on page 2757.

**Configuring Oracle for Unicode**

**How to:**

Set the Environment Variable for NLS_LANG

**Example:**

Setting the NLS_LANG Variable for American English UTF-8

The adapter supports Unicode data in Oracle release 10g or higher databases that have been configured with the NLS_CHARACTERSET parameter set to UTF8. You must set the NLS_LANG environment variable in the edastart file or in a separate shell file.

**Note:**

- Oracle Unicode data in NCHAR/NVARCHAR fields is supported when the reporting server is configured for Unicode.
- The Oracle environment variable ORA_NCHAR_LITERAL_REPLACE controls transparent data conversion into NCHAR/NVARCHAR fields. This variable usually remains unset to maintain better performances.

However, ORA_NCHAR_LITERAL_REPLACE must be set to TRUE in the following rare cases:

- SQL Passthru is used for input into Oracle NCHAR/NVARCHAR fields (INSERT/UPDATE/WHERE clause). The literal must also be in N’<string>’ notation.
- TABLE FILE contains IF/WHERE clause(s) with NCHAR/NVARCHAR field(s).

**Syntax:**

**How to Set the Environment Variable for NLS_LANG**

To set the NLS_LANG environment variable to support Unicode, use the following syntax

```
NLS_LANG = language_territory.characterset
```
where:

*language*

Is the selected language.

*territory*

Is the name of the country associated with the selected language.

*characterset*

Is the value of the NLS_CHARACTERSET variable that is set in the Oracle database. For Unicode, this is always UTF8.

**Example:** Setting the NLS_LANG Variable for American English UTF-8

For American English UTF-8, the following setting is required:

```
NLS_LANG=American_America.UTF8
```

**Configuring the Adapter for Oracle**

**In this section:**

- Declaring Connection Attributes
- Overriding the Default Connection
- Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Example:
Declaring Connection Attributes

Reference:
Connection Attributes for Oracle
Updating the Connection String

In order to connect to an Oracle database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one Oracle database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to Oracle Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
or

From the Data Management Console, expand the Adapters folder.

The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.

The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for Oracle

The Oracle adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Connection name

Is the logical name used to identify this particular set of connection attributes. There is no default connection name. You must provide a value.

TNS name

Service (TNS) name used as a connect descriptor to an Oracle database server across the network. It must point to a valid entry in the tnsnames file.

Connection to a local database server can be entered as <local>. Note that <local> may not have a match in the tnsnames.ora file.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- Explicit. The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- Password Passthru. The user ID and password received from the client application are passed to the database, at connection time, for authentication.
Trusted. The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose **New Profile** from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:**

**How to Declare Connection Attributes Manually**

**Explicit authentication.** The user ID and password are explicitly specified for each connection and passed to Oracle, at connection time, for authentication.

```
ENGINE SQLORA SET CONNECTION_ATTRIBUTES connection TNS_name/userid,password
```

**Password passthru authentication.** The user ID and password are explicitly specified for each connection and passed to Oracle, at connection time, for authentication.

```
ENGINE SQLORA SET CONNECTION_ATTRIBUTES connection TNS_name/
```

**Trusted authentication.** The adapter connects to Oracle as an operating system login using the credentials of the operating system user impersonated by the server data access agent.

```
ENGINE SQLORA SET CONNECTION_ATTRIBUTES connection TNS_name/,
```

where:

**SQLORA**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**

Is a logical name used to identify this particular set of attributes.

Note that one blank space is required between **connection** and TNS_name.
TNS_name

Is the Service (TNS) name used as a connect descriptor to an Oracle database server across the network. It must point to a valid entry in the tnsnames file. Connection to a local database server can be entered as <local>. Note that <local> may not have a match in the tnsnames.ora file.

userid

Is the primary authorization ID by which you are known to Oracle.

gpassword

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command allows the application to access the Oracle database server named SAMPLESERVER, defined in tnsnames.ora as SAMPLESERVER, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

ENGINE SQLORA SET CONNECTION_ATTRIBUTES SAMPLESERVER SAMPLESERVER/MYUSER,PASS

The following SET CONNECTION_ATTRIBUTES command connects to the local Oracle database server and does not use tnsnames:

ENGINE SQLORA SET CONNECTION_ATTRIBUTES <Local> <Local>/MYUSER,PASS

The following SET CONNECTION_ATTRIBUTES command connects to the Oracle database server named SAMPLESERVER using Password Passthru Authentication:

ENGINE SQLORA SET CONNECTION_ATTRIBUTES SAMPLESERVER SAMPLESERVER/

The following SET CONNECTION_ATTRIBUTES command connects to a local Oracle database server using operating system authentication:

ENGINE SQLORA SET CONNECTION_ATTRIBUTES SAMPLESERVER SAMPLESERVER/,

Reference: Updating the Connection String

The syntax for the SET CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.
The Web Console Migrate option migrates your server settings to the newer release. To access this option, select Workspace, then Configuration/Monitor from the menu bar. Right-click Migrate from the Server folder in the navigation pane, and select Configure. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the Migrate button. This is the recommended approach.

If you choose not to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=value.

For example, suppose that prior 7.6.1 the connection was defined as:

```engine
ENGINE SQLORA SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
```

When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

```text
CONNECTION=DSN_A
```

If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

```engine
ENGINE SQLORA SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
```

### Overriding the Default Connection

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:**

```engine
ENGINE SQLORA SET DEFAULT_CONNECTION connection
```
where:

**SQLORA**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

FOC1671, Command out of sequence

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  FOC1671, Command out of sequence.

**Example:**  **Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

ENGINE SQLORA SET DEFAULT_CONNECTION SAMPLENAME

**Controlling the Connection Scope**

**How to:**
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:**  **How to Control the Connection Scope**

ENGINE SQLORA SET AUTODISCONNECT ON {FIN | COMMAND | COMMIT}

**where:**

**SQLORA**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
**FIN**

Disconnects automatically only after the session has been terminated. FIN is the default value.

**COMMAND**

Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

**COMMIT**

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

---

**Managing Oracle Metadata**

**In this section:**
- Creating Synonyms
- Accessing Multiple Database Servers in One SQL Request
- Oracle Data Type Support
- Controlling the Mapping of Large Character Data Types
- Controlling the Mapping of Variable-Length Data Types
- Considerations for the CHAR and VARCHAR2 Data Types
- Trailing Blanks in SQL Expressions
- Changing the Precision and Scale of Numeric Columns
- Considerations for the NUMBER Data Type

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Oracle data types.
Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Sample Generated Synonym

**Reference:**
Synonym Creation Parameters for Oracle
Mapping Oracle Comments into a Synonym
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each Oracle table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Note that creating a synonym for a stored procedure is described with reporting against a stored procedure, in *Generating a Synonym for a Stored Procedure* on page 1683.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   
   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   
   The *Select adapter to configure* or *Select connection to create synonym* pane opens.

3. Click a connection for the configured adapter.
   
   The first of a series of synonym creation panes opens.
4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

Reference: Synonym Creation Parameters for Oracle

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Location of External SQL Scripts**

If you specify **External SQL Scripts** in the **Restrict Object type to** field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the **Base Location** field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the **Document Name** field, enter the file name with or without wildcard characters.

- In the **Document Extension** field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the **Base Location** field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The **Document Extension** is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```text
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the **Cardinality** check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
With foreign key

Select the With foreign key check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

Dynamic columns

To specify that the Master File created for the synonym should not contain column information, select the Dynamic columns check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

For Subquery

Only available when External SQL Scripts is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Oracle Data Type Support on page 1670.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.
Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Oracle synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

FILE=DIVISION, SUFFIX=SQLORA ,$
SEGNAME=SEG1_4, SECTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON ,$

Generated Access File nf29004.acx

SEGNAME=SEG1_4, TABLENAME=EDAQA.NF29004,
CONNECTION=ORA901, KEYS=1, WRITE=YES,$

Reference: Mapping Oracle Comments into a Synonym

When you generate a synonym for an Oracle table, the adapter maps each:

- Oracle table comment from the Oracle data dictionary to a Remark attribute in the Master File of the synonym.
- Oracle column comment from the Oracle data dictionary to a Description attribute in the Master File of the synonym.
**Reference: Access File Keywords**

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the Oracle table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: <code>TABLENAME=[owner.]table[@databaselink]</code></td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is: <code>CONNECTION=connection</code> <code>CONNECTION=' '</code> indicates access to the local Oracle database server. Absence of the CONNECTION attribute indicates access to the default database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first ( n ) fields in the Master File segment. <strong>Note:</strong> If the table does not have the primary key, then the first unique index may be taken instead.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>KEYFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td>IXFLD</td>
<td><em>Note:</em> An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.</td>
</tr>
</tbody>
</table>
**Reference:** Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the <em>Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS</em> manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Accessing Multiple Database Servers in One SQL Request**

To access a remote Oracle table using DATABASE LINKs, the following conditions must exist:

- The Oracle database server to which you are connected must have a valid DATABASE LINK defined.
The `TABLENAME` attribute in the Access File for the Oracle table to be queried must have the following format:

```
TABLENAME=[owner.]table@databaselink
```

where:

- `owner`  
  Is the user ID by default. It can consist of a maximum of 30 characters. Oracle prefers that the value be uppercase.
- `table`  
  Is the name of the table or view. It can consist of a maximum of 30 characters.
- `databaselink`  
  Is the valid DATABASE LINK name defined in the currently connected Oracle database server.

This format for `TABLENAME` can be placed in the Access File manually or using the `CREATE SYNONYM` command. For example:

```
CREATE SYNONYM filename FOR owner.table@databaselink DBMS SQLORA
```

Once you have met the above conditions, all requests for the table will be processed on the remote Oracle database server specified using the DATABASE LINK name. Using this method is another way to access multiple remote servers in one SQL request.

### Oracle Data Type Support

#### Reference:

Data Type Support for Unicode

The following tables describe how the server maps Oracle data types.

<table>
<thead>
<tr>
<th>Oracle Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Date-Time Data Types</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DATE</td>
<td>HYYMDS</td>
<td>Stores point-in-time values (dates and times) ranging from January 1, 4712 BCE through December 31, 9999 CE.</td>
</tr>
</tbody>
</table>
### Oracle Data Type

<table>

</tbody>
</table>
### Oracle Data Type

<table>
<thead>
<tr>
<th>Remarks</th>
<th>Longchar Alpha</th>
<th>Longchar Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Longchar Alpha</td>
<td>Usage</td>
<td>Actual</td>
</tr>
<tr>
<td>n is an integer between 129 and 2000, m = 2 * n</td>
<td>Am</td>
<td>Am</td>
</tr>
</tbody>
</table>

**Note:** The main purpose of the Longchar setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.

**Reference:** Data Type Support for Unicode

The following table describes how the Unicode server maps Character data types. The server operates in character semantic when configured for Unicode. The Longchar does not affect mapping in this case.

<table>
<thead>
<tr>
<th>Oracle Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>AnV</td>
<td>n is an integer between 1 and 2000. The column stores n bytes (specified by the Actual attribute) which represent up to n characters (specified by the Usage attribute).</td>
</tr>
<tr>
<td>CHAR (n CHAR)</td>
<td>An</td>
<td>n is the number of characters, and is an integer between 1 and 2000.</td>
</tr>
<tr>
<td>CHAR (n BYTE)</td>
<td>AnV</td>
<td>n is an integer between 1 and 2000. The column stores n bytes (specified by the Actual attribute) which represent up to n characters (specified by the Usage attribute).</td>
</tr>
<tr>
<td>VARCHAR2 (n) or VARCHAR (n)</td>
<td>AnV</td>
<td>AnVB</td>
</tr>
</tbody>
</table>
**Controlling the Mapping of Large Character Data Types**

**How to:**

Control the Mapping of Large Character Data Types

The SET parameter CONVERSION LONGCHAR controls the mapping of supported Oracle data types listed below. By default, the server maps these data types as alphanumeric (A). The server data type A supports a maximum of 4096 characters for TABLE/MODIFY and 32768 characters for API applications.

**Syntax:**

How to Control the Mapping of Large Character Data Types

```
ENGINE SQLORA SET CONVERSION LONGCHAR {ALPHA | TEXT | BLOB}
```

where:

**SQLORA**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ALPHA**

Maps the Oracle data types CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and RAW as alphanumeric (A). ALPHA is the default value.

**TEXT**

Maps the Oracle data types CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and RAW as text (TX). Use this value for WebFOCUS applications.

<table>
<thead>
<tr>
<th>Oracle Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR2 (n CHAR)</td>
<td>AnV</td>
<td><em>n</em> is the number of characters, and is an integer between 1 and 4000.</td>
</tr>
<tr>
<td></td>
<td>AnV</td>
<td></td>
</tr>
<tr>
<td>VARCHAR2 (n BYTE)</td>
<td>AnV</td>
<td><em>n</em> is an integer between 1 and 4000.</td>
</tr>
<tr>
<td></td>
<td>AnVB</td>
<td>The column stores up to <em>n</em> bytes (specified by the ACTUAL attribute)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>which represent up to <em>n</em> characters (specified by the USAGE attribute).</td>
</tr>
</tbody>
</table>
For UNIX, Windows, OpenVMS, and IBM i, is identical to ALPHA. That is, it maps the Oracle data types CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and RAW as alphanumeric (A).

For z/OS, maps the Oracle data types CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and RAW as binary large object (BLOB).

**Controlling the Mapping of Variable-Length Data Types**

**How to:**
Control the Mapping of Variable-Length Data Types

The SET parameter VARCHAR controls the mapping of the Oracle data types VARCHAR, VARCHAR2, and NVARCHAR2. By default, the server maps these data types as variable character (AnV).

The following table lists data type mappings based on the value of VARCHAR:

<table>
<thead>
<tr>
<th>Oracle Data Type</th>
<th>Remarks</th>
<th>VARCHAR ON</th>
<th>VARCHAR OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>USAGE</td>
<td>ACTUAL</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>n is an integer between 1 and 4000</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>VARCHAR2 (n)</td>
<td>n is an integer between 1 and 4000</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>NVARCHAR2 (n)</td>
<td>n is an integer between 1 and 4000</td>
<td>AmV</td>
<td>AmV</td>
</tr>
</tbody>
</table>

**Syntax:**
How to Control the Mapping of Variable-Length Data Types

```
ENGINE SQLORA SET VARCHAR {ON | OFF}
```

where:

`SQLORA`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
ON

Maps the Oracle data types VARCHAR, VARCHAR2, and NVARCHAR2 as variable-length alphanumeric (AnV). This is required for Unicode environments. ON is the default value.

OFF

Maps the Oracle data types VARCHAR, VARCHAR2, and NVARCHAR2 as alphanumeric (A). ON is the default value.

Considerations for the CHAR and VARCHAR2 Data Types

**How to:**

Set ORACHAR

Special attention must be paid to CHAR and VARCHAR2 data types. When you compare a CHAR data type column to a VARCHAR2 data type column, where the only difference is additional trailing spaces in the CHAR data type column, Oracle treats the column values as different.

The SET parameter lets you specify which of the two data types will be used for inserting, updating, and retrieving data.

If you create the tables outside of the server, we recommend that you use either CHAR or VARCHAR2 data types, but not both. If you create a table with both data types, you might not be able to retrieve the data you inserted due to Oracle’s comparison mechanism. When inserting data into VARCHAR2 columns outside of the server, do not insert any trailing spaces.

If you use the server to generate Oracle tables and retrieve data, you will not encounter this problem, since the data type being used will be either CHAR or VARCHAR2, depending upon the ORACHAR setting.

**Syntax:** **How to Set ORACHAR**

```sql
ENGINE SQLORA SET ORACHAR {FIX | VAR}
```

*where:*

**SQLORA**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**FIX**

Uses the CHAR data type. This is the default value.
VAR

Uses the VARCHAR2 data type.

**Trailing Blanks in SQL Expressions**

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

```sql
ENGINE SQLORA SET TRIM_LITERALS ON
```

is available to ensure backward compatibility.

**Changing the Precision and Scale of Numeric Columns**

**How to:**

Override the Default Precision and Scale

**Example:**

Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

```sql
ENGINE SQLORA SET CONVERSION RESET
ENGINE SQLORA SET CONVERSION format RESET
ENGINE SQLORA SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLORA SET CONVERSION format [PRECISION MAX]
```

where:

**SQLORA**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
RESET

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**

Is any valid format supported by the data source. Possible values are:

- **INTEGER** which indicates that the command applies only to INTEGER columns.
- **DECIMAL** which indicates that the command applies only to DECIMAL columns.
- **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.

- **FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>
**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.

**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```
ENGINE SQLORA SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```
ENGINE SQLORA SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```
ENGINE SQLORA SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```
ENGINE SQLORA SET CONVERSION RESET
```

**Considerations for the NUMBER Data Type**

**How to:**

Set ORANUMBER

When working with the NUMBER data type, where the precision is between 1 and 31, and scale is not negative and does not exceed precision, the data type is mapped to the server data type decimal (P) of corresponding precision and scale. Note that the resulting display length has to accommodate for sign and possible decimal point, thus it will exceed precision by 1 or 2.
When the NUMBER data type has precision 38 and scale 0, by default the data type is mapped to the server data type Integer (I), with a display length of 11.

Otherwise, by default, the NUMBER data type is mapped to the server data type double float (D), with a precision of 20 and a scale of 2.

Use the ORANUMBER setting to override the default mapping of the NUMBER data type, where the precision is between 32 and 38 and scale is not negative.

**Syntax:**

**How to Set ORANUMBER**

```
ENGINE SQLORA SET ORANUMBER {COMPAT | DECIMAL}
```

where:

**SQLORA**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE=SQLORA command.

**COMPAT**

Indicates that the NUMBER data type will be mapped using the default behavior described above.

**DECIMAL**

When NUMBER data type has precision between 32 and 38 and scale is not negative, the NUMBER data type precision (and possibly scale) will be truncated down to 31 prior to mapping, and then the data type will be mapped to the server data type decimal (P) as described above.

**Reporting Against an Oracle Stored Procedure**

**In this section:**

Generating a Synonym for a Stored Procedure

Creating a Report Against a Stored Procedure

You can use a reporting tool, such as a SELECT statement or TABLE command, to execute Oracle stored procedures and report against procedure output parameters and answer set. Among the benefits of this method of executing a stored procedure are:

- The retrieval of output parameters (OUT parameters, and INOUT parameters in OUT mode), as well as the answer set. (Other methods of invocation retrieve the answer set only.)

- The ease with which you can process, format, and display output parameters and the answer set, using TABLE and other reporting tools.
To report against a stored procedure:

1. **Generate a synonym** for the stored procedure answer set, as described in *Generating a Synonym for a Stored Procedure* on page 1683.

2. **Create a report procedure**, as described in *Creating a Report Against a Stored Procedure* on page 1686.

3. **Run the report.** This executes the stored procedure and reports against any output parameters (OUT and INOUT in OUT mode), and any answer set fields, specified in the report.

### Generating a Synonym for a Stored Procedure

**Reference:**

Synonym Creation Parameters for Stored Procedures

A synonym describes the parameters and answer set of a stored procedure.

An answer set’s structure may vary depending on the input parameter values that are provided when the procedure is executed. Therefore, you need to generate a separate synonym for each set of input parameter values that will be provided when the procedure is executed at run time. For example, if users may execute the stored procedure using three different sets of input parameter values, you need to generate three synonyms, one for each set of values. (Unless noted otherwise, "input parameters" refers to IN parameters and to INOUT parameters in IN mode.)

**There is an exception:** if you know the procedure’s internal logic, and are certain which range of input parameter values will generate each answer set structure returned by the procedure, you can create one synonym for each answer set structure, and for each synonym simply provide a representative set of the input parameter values necessary to return that answer set structure.

A synonym includes the following segments:

- **INPUT**, which describes any IN parameters and INOUT parameters in IN mode.
  
  If there are no IN parameters or INOUT parameters in IN mode, the segment describes a single dummy field.

- **OUTPUT**, which describes any OUT parameters and INOUT parameters in OUT mode.
  
  If there are no OUT parameters or INOUT parameters in OUT mode, the segment is omitted.

- **ANSWERSETn**, one for each answer set.
  
  If there is no answer set, the segment is omitted.
### Reference: Synonym Creation Parameters for Stored Procedures

<table>
<thead>
<tr>
<th>Parameter/Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restrict Object Type to</td>
<td>Select Stored Procedures.</td>
</tr>
<tr>
<td>Filter by Owner/Schema and Object name</td>
<td>Selecting this option adds the Owner/Schema and Object Name parameters to the screen. <strong>Owner/Schema.</strong> Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end. <strong>Object name.</strong> Type a string for filtering the procedure names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all procedures whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.</td>
</tr>
<tr>
<td>Select</td>
<td>Select a procedure. You may only select one procedure at a time since each procedure will require unique input in the Values box on the next synonym creation pane.</td>
</tr>
<tr>
<td>Name</td>
<td>The name of the synonym, which defaults to the stored procedure name.</td>
</tr>
<tr>
<td>Select Application</td>
<td>Select an application directory. The default value is baseapp.</td>
</tr>
<tr>
<td>Prefix/Suffix</td>
<td>If you have stored procedures with identical names, assign a prefix or a suffix to distinguish their corresponding synonyms. Note that the resulting synonym name cannot exceed 64 characters. If all procedures have unique names, leave the prefix and suffix fields blank.</td>
</tr>
<tr>
<td><strong>Parameter/Task</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Overwrite Existing Synonyms</td>
<td>To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the <em>Overwrite existing synonyms</em> check box.</td>
</tr>
<tr>
<td>Customize data type mappings</td>
<td>To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed. For information about them, see <a href="#">Data Type Support</a> in the chapter for your adapter in the <em>Adapter Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS</em> manual.</td>
</tr>
<tr>
<td>Values</td>
<td>Select the check box for every parameter displayed for the specified procedure.</td>
</tr>
</tbody>
</table>

Note the following before you enter parameter values: if the procedure you selected has input parameters (IN parameters and/or INOUT parameters in IN mode), you will be prompted to enter values for them. However, the need for an explicit Value entry depends on the logic of the procedure and the data structures it produces. Therefore, while you must check the parameter box, you may not need to enter a value. Follow these guidelines:

- Explicit input values (and separate synonyms) are required when input parameter values cause answer sets with different data structures, which vary depending on the input parameters provided.

- Explicit input values are not required when you know the procedure’s internal logic and are certain that it always produces the same data structure. In this situation, only one synonym needs to be created and you can leave the Value input blank for synonym-creation purposes.

If a Value is required, enter it without quotes. Any date, date-time, and timestamp parameters must have values entered in an ISO format. Specify the same input parameters that will be provided when the procedure is executed at run time if it is a procedure that requires explicit values.
Creating a Report Against a Stored Procedure

How to:

Report Against a Stored Procedure Using the TABLE Command
Report Against a Stored Procedure Using SELECT

You can report against a stored procedure's answer set using the same facilities you use to report against a database table:

- **SQL SELECT statement.** For syntax, see *How to Report Against a Stored Procedure Using SELECT* on page 1687.

- **TABLE and GRAPH commands.** For syntax, see *How to Report Against a Stored Procedure Using the TABLE Command* on page 1686.

When joining from or to a stored procedure answer set, you can:

- **Join from** only OUTPUT and ANSWERSET segments in a host file.
- **Join to** only INPUT segments in a cross-referenced file.

**Syntax:**  How to Report Against a Stored Procedure Using the TABLE Command

To execute a stored procedure using the TABLE command, use the following syntax

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
.
.
END
```

**where:**

- **synonym**

  Is the synonym of the stored procedure you want to execute.

- **parameter**

  Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.

  If the stored procedure does not require parameters, specify an asterisk (*). This displays a dummy segment, created when the synonym is generated, to satisfy the structure of the SELECT statement.
* Indicates that you want to display all indicated parameters, or that there are no required parameters.

**IF**

Is an IF or WHERE keyword. Use this to pass a value to an IN parameter or an INOUT parameter in IN mode.

**in-parameter**

Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

**Note:** The length of in-parameters cannot exceed 1000 characters if the adapter is configured for Unicode support.

**value**

Is the value you are passing to a parameter.

**Syntax:** How to Report Against a Stored Procedure Using SELECT

```sql
SQL
SELECT [parameter [,parameter] ... | *] FROM synonym
[WHERE in-parameter = value]
.
.
.
END
```

where:

**synonym**

Is the synonym of the stored procedure that you want to execute.

**parameter**

Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, enter an asterisk (*) in the syntax. This displays a dummy segment, created during synonym generation, to satisfy the structure of the SELECT statement.

* Indicates that you want to display all indicated parameters, or that there are no required parameters.
WHERE

Is used to pass a value to an IN parameter or an INOUT parameter in IN mode.
You must specify the value of each parameter on a separate line.

in-parameter

Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

value

Is the value you are passing to a parameter.

Customizing the Oracle Environment

In this section:
Choosing a Source for System Date and Time
Designating a Default Tablespace
Overriding Default Parameters for Index Space
Activating NONBLOCK Mode
Obtaining the Number of Rows Updated or Deleted
Specifying the Maximum Number of Parameters for Stored Procedures

The Adapter for Oracle provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.

Choosing a Source for System Date and Time

How to:
Choose a Source for System Date and Time

When an SQL SELECT statement refers to CURRENT_DATE, CURRENT_TIME, or CURRENT_TIMESTAMP, it will obtain the date or time value from the Server (the default), or from the Oracle DBMS. You can override the default using the new SET DATETIME_PROCESS option. This is effective only for reports using Automatic Passthru.
**Syntax:**  
**How to Choose a Source for System Date and Time**

To choose a source for system date and time, the syntax is

```
SQL SET DATETIME_PROCESS=SERVER|DBMS
END
```

where:

- **SERVER**
  - Specifies that the date and time values will be taken from the Server. This is the default.
- **DBMS**
  - Specifies that the date and time values will be taken from the Oracle DBMS.

**Designating a Default Tablespace**

**How to:**

Set DBSPACE

You can use the SET DBSPACE command to designate a default tablespace for tables you create. For the duration of the session, the adapter places these tables in the Oracle tablespace that you identify with the SET DBSPACE command. If the SET DBSPACE command is not used, Oracle uses the default tablespace for the connected user.

**Syntax:**  
**How to Set DBSPACE**

```
ENGINE SQLORA SET DBSPACE tablespace
```

where:

- **SQLORA**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
- **tablespace**
  - Is a valid tablespace in the database.

**Note:** This command will affect only CREATE FILE and HOLD FORMAT SQLORA requests issued by Table Services. It does not affect Passthru CREATE TABLE commands.
Overriding Default Parameters for Index Space

**How to:**

Set IXSPACE

You can use the SET IXSPACE command to override the default parameters for the index space implicitly created by the CREATE FILE and HOLD FORMAT commands.

**Syntax:**

**How to Set IXSPACE**

ENGINE SQLORA SET IXSPACE

where:

SQLORA

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

index-spec

Is the portion of the Oracle CREATE INDEX statement that defines the parameters for the index. It can consist of up to 94 bytes of valid Oracle index space parameters. To reset the index space parameters to their default values, issue the SET IXSPACE command with no parameters.

**Note:** Refer to the Oracle documentation for more information on this command.

The long form of SQL Passthru syntax for commands exceeding one line is:

ENGINE SQLORA
SET IXSPACE index-spec
END

For example, to specify the NOSORT, NOLOGGING, and TABLESPACE portions of the Oracle CREATE INDEX statement, enter the following commands:

ENGINE SQLORA
SET IXSPACE NOSORT NOLOGGING
TABLESPACE TEMP
END
**Note:** This command will only affect CREATE INDEX requests issued by CREATE FILE and HOLD FORMAT SQLORA commands. It does not affect Passthru CREATE INDEX commands, for example:

```sql
ENGINE SQLORA SET IXSPACE TABLESPACE tablespace_name
TABLE FILE table_name
PRINT *
ON TABLE HOLD AS file_name FORMAT SQLORA
END
```

### Activating NONBLOCK Mode

#### How to:

Activate NONBLOCK Mode

The Adapter for Oracle has the ability to issue calls in NONBLOCK mode. The default behavior is BLOCK mode.

This feature allows the adapter to react to a client request to cancel a query while the adapter is waiting on engine processing. This wait state usually occurs during SQL parsing, before the first row of an answer set is ready for delivery to the adapter or while waiting for access to an object that has been locked by another application.

**Tip:** You can change this setting manually or from the Web Console by clicking **Data Adapters** on the menu bar, clicking a configured adapter, and choosing **Change Settings** from the menu. The Change Settings pane opens.

#### Syntax: How to Activate NONBLOCK Mode

```sql
ENGINE SQLORA SET NONBLOCK \{0|n\}
```

where:

**SQLORA**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**n**

Is a positive numeric number. 0 is the default value, which means that the adapter will operate in BLOCK mode. A value of 1 or greater activates the NONBLOCK calling and specifies the time, in seconds, that the adapter will wait between each time it checks to see if the:

- Query has been executed.
- Client application has requested the cancellation of a query.
A value of 1 or 2 should be sufficient for normal operations.

Obtaining the Number of Rows Updated or Deleted

**How to:**
Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:** How to Obtain the Number of Rows Updated or Deleted

ENGINE SQLORA SET PASSRECS {ON | OFF}

where:

<table>
<thead>
<tr>
<th><strong>SQLORA</strong></th>
<th>Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ON</strong></td>
<td>Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.</td>
</tr>
<tr>
<td><strong>OFF</strong></td>
<td>Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.</td>
</tr>
</tbody>
</table>

Specifying the Maximum Number of Parameters for Stored Procedures

**How to:**
Set SMAXPRM

You can use the SET SMAXPRM command to specify the maximum number of input parameters that can be associated with any Oracle stored procedure.
**Syntax:**

How to Set SPMAXPRM

`ENGINE SQLORA SET SPMAXPRM nnn`

where:

**SQLORA**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**nnn**

Is the maximum number of parameters that can be passed to any stored procedure available to be run in this client session. 256 is the default value.

**Optimization Settings**

**In this section:**

- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields
- Optimizing Requests if a Virtual Field Contains Null Values
- Optimizing Requests to Pass Virtual Fields Defined as Constants
- Specifying Block Size for Retrieval Processing
- Improving Efficiency With Aggregate Awareness
- Optimizing Non-equality WHERE-based Left Outer Joins

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

How to:
Optimize Requests

Example:
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

Reference:
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

```
SQL SQLORA SET {OPTIMIZATION|SQLJOIN} setting
```

where:

SQLORA

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

SQLJOIN

Is a synonym for OPTIMIZATION.

setting

Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example: SQL Requests Passed to the RDBMS With Optimization OFF**

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```sql
SQL SQLORA SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
   SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
   IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```plaintext
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
   FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
   FOR FETCH ONLY;
```

**Example: SQL Requests Passed to the RDBMS With Optimization ON**

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```sql
SQL SQLORA SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
   SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
   IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

```sql
AGGREGATION DONE ...
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'. 'EMPINFO' T1,'USER1'. 'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID, T1.LN
ORDER BY T2.EID, T1.LN;
```

**Reference: SQL Generation in Optimization Examples**

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:**

Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**

Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax: How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields**

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLORA SET OPTIFTHENELSE {ON | OFF}
```
where:

**SQLORA**

Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Enables IF-THEN-ELSE optimization. This is the default.

**OFF**

Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:**  **Using IF-THEN_ELSE Optimization Without Aggregation**

Consider the following request:

```sql
SQL SQLORA SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') 
    AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN',T1.'FN',T1.'DPT' FROM USER1.'EMPINFO' T1 
WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' '))
    AND (T1.'DPT' = 'MIS'))));
```
**Example: Using IF-THEN_ELSE Optimization With Aggregation**

Consider the following request:

```sql
SQL SQLORA SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
   ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
  WHERE (((T1.'LN' = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
  WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

**Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False**

```sql
SQL SQLORA SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
Reference: **SQL Limitations on Optimization of DEFINE Expressions**

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  \[ X = X + 1; \]
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

**Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
- If Oracle character data is stored in an NCHAR or NVARCHAR2 field, you must construct a DEFINE expression to avoid a character set mismatch (ORA-12704) and ensure optimization of the DEFINE. In the IF expression, place the search-string to the left of the comparison operator (EQ, GT, LE) and the field with the data type of NCHAR(n) or NVARCHAR2(n) to the right of the comparison operator.
The following example illustrates this technique using the search string 'BOSTON', the EQ operator, and the LOC field, which is mapped from the Oracle data type NCHAR(n) or NVARCHAR2(n):

```
DEFINE FILE DEPT
  DNUM/D20.2= IF `BOSTON` EQ LOC THEN 1 ELSE 0;
END
```

Optimizing Requests if a Virtual Field Contains Null Values

**How to:**
Set Enhanced Aggregation Control

**Example:**
Optimizing Aggregation Requests

The SET OPTNOAGGR command provides finely-tuned control of adapter behavior for optimization. Users who for any reason wish to prevent passing aggregation to the RDBMS can use this command. An example of such a reason might be where NULL values occur in aggregated data with calculations. The SET OPTNOAGGR command causes the adapter to generate SQL without passing aggregation to the DBMS. Aggregation is instead performed internally by the server while JOIN and SORT operations are handled by the RDBMS.

If any DEFINE field contains calculations with NULL fields then such operations cannot be translated to SQL and pass to DBMS because always return NULL. It has to be processed by FOCUS.

This can be achieved by SET OPTIMIZATION OFF.

However, in some cases it is preferable to use the off-load JOIN and SORT operation to DBMS for better performance while leaving AGGREGATION to FOCUS.

**Syntax:**

```
SQL SQLORA SET OPT {AGGR|NOAGGR}
```

where:

**AGGR**

Directs the adapter to off-load aggregated DEFINE fields to the DBMS. This is default setting.
NOAGGR

Directs the adapter to generate SQL without passing aggregation to the DBMS. Aggregation is, instead, performed internally by the server, while JOIN and SORT operations are handled by the RDBMS. This setting can also be used to provide backwards compatibility for applications that were written based on the functionality of the previous release, when less SQL was off-loaded to the RDBMS. For example, when a calculation on aggregated fields may have contained NULL data that was not processed by the RDBMS NVL() function.

Example: Optimizing Aggregation Requests

The following example is based on the SCOTT.EMP SCOTT.DEPT demo Oracle tables.

```
JOIN CLEAR
JOIN DEPTNO IN EMP TO DEPTNO IN DEPT TAG D AS J1
DEFINE FILE EMP
LOC_FLAG/I2 = IF LOC EQ 'CHICAGO' THEN 1 ELSE 0 ;
BONUS_NEW/D15.2 = ((SAL + COMM)/2) * .2 ;
BONUS_BASE/D15.2 = (SAL + COMM) ;
END
TABLE FILE EMP
SUM COMM SAL BONUS_NEW MAX.LOC
FST.LOC_FLAG BONUS_BASE
- *
BY DNAME
BY ENAME
- *
ON TABLE HOLD
END
-RUN
TABLE FILE HOLD
PRINT *
END
```

With OPTIMIZATION ON, the default OPT AGGR adapter generates SQL, and if COMM is NULL, performs calculations in dbms and return 0 to report:

```
18.01.35 AE SELECT T2."DNAME",T1."ENAME", SUM(T1."COMM"), SUM(T1."SAL"),
18.01.35 AE SUM(((T1."SAL" + T1."COMM") / 2) * .2)), MAX(T2."LOC"),
18.01.35 AE MIN((CASE (T2."LOC") WHEN 'CHICAGO' THEN 1 ELSE 0 END)),
18.01.35 AE SUM((T1."SAL" + T1."COMM")) FROM EMP T1,DEPT T2 WHERE
18.01.35 AE (T2."DEPTNO" = T1."DEPTNO") GROUP BY T2."DNAME",T1."ENAME"
18.01.35 AE ORDER BY T2."DNAME",T1."ENAME";
```

This behavior can be overcome in two ways:

- Use SET OPTIMIZATION OFF to direct the adapter sent to dbms to use the most basic (atomic) SQL and put maximum processing on FOCUS.
or

- Use SET OPT NOAGGR to pass JOIN to DBMS and leave aggregation to FOCUS, avoiding NULL calculations. Generated SQL still passes JOIN to Oracle to significantly improve performance:

```
```

### Optimizing Requests to Pass Virtual Fields Defined as Constants

<table>
<thead>
<tr>
<th>Example:</th>
<th>Passing Numeric Constants</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Passing a CHAR Constant</td>
</tr>
<tr>
<td></td>
<td>Passing CHAR and INTEGER Constants</td>
</tr>
</tbody>
</table>

A virtual field defined as a constant is passed directly to an SQL database engine (RDBMS) for optimized processing that takes advantage of RDBMS join, sort, and aggregation capabilities, thus reducing the volume of RDBMS-to-server communication and improving response time. (In prior releases, constants were not passed to the database engine, causing optimization to be turned off.)

Constants in the following formats are passed to the RDBMS: NUMERIC, CHAR, VARCHAR, CHAR/INTEGER combination, and DATE. (Note that a few formats are not passed to the RDBMS; these are CHAR and VARCHAR combination, TIME, and DATETIME.)

When valid constants are passed to an RDBMS engine, a report is calculated based on the defined value(s) and only the calculated subset of records is returned. The extent of data manipulation at the adapter level is limited, thereby improving performance.

<table>
<thead>
<tr>
<th>Example:</th>
<th>Passing Numeric Constants</th>
</tr>
</thead>
</table>

```
DEFINE FILE SMIX87
INTEGERCONST/I4 = 5
REALCONST/D20.2 = -97995.38
NUMERICCONST/P13.4 = -92999.3647

TABLE FILE SMIX87
SUM INTEGERCONST REALCONST NUMERICCONST MAX.QUOT.FA01INTEGER
BY QUOT.FA02INTEGER
END
```
The following SQL is generated:

```
SELECT T2."FA02INTEGER", SUM(5), SUM(-97995.38),
       SUM(-92999.3647), MAX(T2."FA01INTEGER") FROM TMIX83A T2 GROUP
       BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Example: Passing a CHAR Constant**

DEFINE FILE SMIX87
  CHARCONST/A10 = '2N'

TABLE FILE SMIX87
  SUM CHARCONST MIN.FA02CHAR_15
  BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), MIN(T3."FA02CHAR_15") FROM
       TMIX83A T2,TMIX86A T3 WHERE (T3."FA01INTEGER" =
       T2."FA01INTEGER") GROUP BY T2."FA02INTEGER" ORDER BY
       T2."FA02INTEGER";
```

**Example: Passing CHAR and INTEGER Constants**

DEFINE FILE SMIX87
  CHARCONST/A10 = '2N'
  INTEGERCONST/I4 = 5

TABLE FILE SMIX87
  SUM CHARCONST INTEGERCONST
  BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), SUM(5) FROM TMIX83A T2
       GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Specifying Block Size for Retrieval Processing**

**How to:**

- Specify the Block Size for Array Retrieval
- Specify the Block Size for Insert Processing

The Adapter for Oracle supports array retrieval from result sets produced by executing SELECT queries or stored procedures. This technique substantially reduces network traffic and CPU utilization.
Using high values increases the efficiency of requests involving many rows, at the cost of higher virtual storage requirements. A value higher than 100 is not recommended because the increased efficiency it would provide is generally negligible.

**Tip:** You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

**Syntax:**  
**How to Specify the Block Size for Array Retrieval**

The block size for a SELECT request applies to TABLE FILE requests, MODIFY requests, MATCH requests, and DIRECT SQL SELECT statements.

```
ENGINE SQLORA SET FETCHSIZE n
```

where:

- **SQLORA**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **n**
  - Is the number of rows to be retrieved at once using array retrieval techniques. Accepted values are 1 to 5000. The default varies by adapter. If the result set contains a column that has to be processed as a CLOB or a BLOB, the FETCHSIZE value used for that result set is 1.

**Syntax:**  
**How to Specify the Block Size for Insert Processing**

In combination with LOADONLY, the block size for an INSERT applies to MODIFY INCLUDE requests. INSERTSIZE is also supported for parameterized DIRECT SQL INSERT statements.

```
ENGINE SQLORA SET INSERTSIZE n
```

where:

- **SQLORA**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **n**
  - Is the number of rows to be inserted using array insert techniques. Accepted values are 1 to 5000. 1 is the default value. If the result set contains a column that has to be processed as a BLOB, the INSERTSIZE value used for that result set is 1.
Improving Efficiency With Aggregate Awareness

**How to:**
Set Aggregate Awareness

Aggregate awareness substantially improves the efficiency of queries.
For details about this feature, see *Aggregate Awareness Support* on page 2763.

**Syntax:**

**How to Set Aggregate Awareness**

```sql
SET AGGREGATE_AWARENESS {FRESH_ONLY|OLD_OK|OFF}
```

where:

- **FRESH_ONLY**
  Sets different values for the parameters associated with each RDBMS.

- **OLD_OK**
  Sets different values for the parameters associated with each RDBMS.

- **OFF**
  If no option is selected, the behavior of the target RDBMS is determined by the database configuration options. There is no default for this setting.

For details about adapter-specific settings, see *Usage Notes for Aggregate Awareness* on page 2765.
Optimizing Non-equality WHERE-based Left Outer Joins

**How to:**
Specify a Conditional Left Outer JOIN

**Example:**
Optimizing a Non-Equality Left-Outer Join

**Reference:**
Conditions for WHERE-Based Outer Join Optimization

A left outer join selects all records from the host table and matches them with records from the cross-referenced table. When no matching records exist, the host record is still retained, and default values (blank or zero) are assigned to the cross-referenced fields. The adapter can optimize any WHERE-based left outer join command in which the conditional expression is supported by the RDBMS.

**Syntax:**  How to Specify a Conditional Left Outer JOIN

```
JOIN LEFT_OUTER FILE hostfile AT hfld1 [TAG tag1]
    [WITH hfld2]
    TO {UNIQUE|MULTIPLE}
    FILE crfile AT crfld [TAG tag2] [AS joinname]
    [WHERE expression1;]
    [WHERE expression2;]
    [...]
END
```

where:

**LEFT_OUTER**
Specifies a left outer join. If you do not specify the type of join in the JOIN command, the ALL parameter setting determines the type of join to perform.

**hostfile**
Is the host Master File.

**AT**
Links the correct parent segment or host to the correct child or cross-referenced segment. The field values used as the AT parameter are not used to cause the link. They are used as segment references.
**hfld1**

Is the field name in the host Master File whose segment will be joined to the cross-referenced data source. The field name must be at the lowest level segment in its data source that is referenced.

**tag1**

Is the optional tag name that is used as a unique qualifier for fields and aliases in the host data source.

**WITH hfld2**

Is a data source field with which to associate a DEFINE-based conditional JOIN. For a DEFINE-based conditional join, the KEEPDEFINES setting must be ON, and you must create the virtual fields before issuing the JOIN command.

**MULTIPLE**

Specifies a one-to-many relationship between `from_file` and `to_file`. Note that ALL is a synonym for MULTIPLE.

**UNIQUE**

Specifies a one-to-one relationship between `hostfile` and `crfile`. Note that ONE is a synonym for UNIQUE.

**Note:** Unique returns only one instance and, if there is no matching instance in the cross-referenced file, it supplies default values (blank for alphanumeric fields and zero for numeric fields).

The unique join is a WebFOCUS concept. The RDBMS makes no distinction between unique and non-unique situations. It always retrieves all matching rows from the cross-referenced file.

If the RDBMS processes a join that the request specifies as unique, and if there are, in fact, multiple corresponding rows in the cross-referenced file, the RDBMS returns all matching rows. If, instead, optimization is disabled so that WebFOCUS processes the join, a different report results because WebFOCUS, respecting the unique join concept, returns only one cross-referenced row for each host row.

**crfile**

Is the cross-referenced Master File.

**crfld**

Is the join field name in the cross-referenced Master File. It can be any field in the segment.
tag2

Is the optional tag name that is used as a unique qualifier for fields and aliases in the cross-referenced data source.

joinname

Is the name associated with the joined structure.

eexpression1, expression2

Are any expressions that are acceptable in a DEFINE FILE command. All fields used in the expressions must lie on a single path.

Reference: Conditions for WHERE-Based Outer Join Optimization

- In order for a WHERE-based left outer join to be optimized, the expressions must be optimizable for the RDBMS involved and at least one of the following conditions must be true:
  - The JOIN WHERE command contains at least one field1 EQ field2 predicate in which field1 is in table1 and field2 is in table2.
    - or
  - The right table has a key or a unique index that does not contain NULL data.
    - or
  - The right table contains at least one "NOT NULL" column that does not have a long data type (such as TEXT or IMAGE).
- The adapter SQLJOIN OUTER setting must be ON (the default).
Example: Optimizing a Non-Equality Left-Outer Join

The following request creates a left outer conditional join between two Oracle data sources and reports against the joined data sources. The STMTRACE is turned on in order to view the SQL generated for this request:

```
SET TRACEUSER = ON
SET TRACEOFF = ALL
SET TRACEON = STMTRACE//CLIENT
JOIN LEFT_OUTER FILE baseapp/EQUIP AT CARS
TO ALL FILE baseapp/CARREC AT CARC
WHERE CARS NE CARC;
END
```

The WebFOCUS request is translated to a single Oracle SELECT statement that incorporates the left outer join, and the non-equality condition is passed to the RDBMS in the ON clause:

```
SELECT T1."CARS"(CHAR( 16)),T1."STANDARD"(CHAR( 40)),
T2."CARC"(CHAR( 16)),T2."MODEL"(CHAR( 24)) FROM ( EQUIP T1
LEFT OUTER JOIN CARREC T2 ON (T1."CARS" <> T2."CARC") ) ORDER BY
T2."MODEL";
```

Calling an Oracle Stored Procedure Using SQL Passthru

**How to:**

Invoke a Stored Procedure

**Example:**

An Oracle Stored Procedure With REF_CURSOR

An Oracle Stored Procedure Without REF_CURSOR

Using SQL Passthru is supported for Oracle stored procedures. These procedures need to be developed within Oracle using the CREATE PROCEDURE command.

**Note:** Calling a stored procedure using SQL Passthru only allows the processing of one answer set per invocation. If multiple answer sets are expected, the CREATE SYNONYM mechanism is preferred.
How to Invoke a Stored Procedure

**Syntax:**

```
SQL SQLORA EX proname [parameter_specification1]
[,parameter_specification2]...
END
```

where:

**SQLORA**

Is the ENGINE suffix for Oracle.

**proname**

Is the name of the stored procedure. It is the fully or partially qualified name of the stored procedure in the native RDBMS syntax.

**parameter_specification**

IN, OUT, and INOUT parameters are supported. Use the variation required by the stored procedure:

**IN**

Is a literal (for example, 125, 3.14, 'abcde'). You can use reserved words as input. Unlike character literals, reserved words are not enclosed in quotation marks (for example, NULL). Input is required.

**OUT**

Is represented as a question mark (?). You can control whether output is passed to an application by including or omitting this parameter. If omitted, this entry will be an empty string (containing 0 characters).

**INOUT**

Consists of a question mark (?) for output and a literal for input, separated by a slash: / (For example: ?/125, ?/3.14, ?/'abcde'.) The out value can be an empty string (containing 0 characters).

The adapter supports invocation of stored procedures that conform to the following rules:

- All scalar parameters (IN, OUT, and INOUT) are supported.
- A cursor must be defined with:
  - The TYPE statement in a PACKAGE or PROCEDURE.
  - An associated record layout of the answer set to be returned.
- The cursor must be opened in the procedure.
- No fetching is allowed in the stored procedure. The adapter fetches the answer set.
Any messages must be issued using the RAISE APPLICATION ERROR method.

If any parameters are declared as RECORD, and those parameters are associated with REFCURSOR, then when invoking the stored procedure using SQL Passthru do not specify those parameters. For an example, see An Oracle Stored Procedure With REFCURSOR on page 1711.

Any application error that is issued by the stored procedure is available in the server variable &ORAMSGTXT.

**Example:** An Oracle Stored Procedure With REFCURSOR

The following Oracle stored procedure uses REFCURSOR. You must create it in SQL*Plus using PL/SQL.

```sql
sqlplus scott/tiger
set serveroutput on
CREATE OR REPLACE PACKAGE pack1 AS
  TYPE nfrectype IS RECORD (employee NF29005.EMPLOYEE_ID5%TYPE,
                           ssn5     NF29005.SSN5%TYPE,
                           l_name   NF29005.LAST_NAME5%TYPE,
                           f_name   NF29005.FIRST_NAME5%TYPE,
                           birthday NF29005.BIRTHDATE5%TYPE,
                           salary   NF29005.SALARY5%TYPE,
                           joblevel NF29005.JOB_LEVEL5%TYPE);
  TYPE nfcurtype IS REF CURSOR RETURN nfrectype;
  PROCEDURE proc1(c_saltable IN OUT nfcurtype);
END pack1;
/
show error
CREATE OR REPLACE PACKAGE BODY pack1 AS
  PROCEDURE proc1 (c_saltable IN OUT nfcurtype)
  IS
    BEGIN
      OPEN c_saltable FOR SELECT EMPLOYEE_ID5,SSN5,LAST_NAME5,FIRST_NAME5,
                     BIRTHDATE5, SALARY5, JOB_LEVEL5 FROM NF29005;
      END proc1; -- end of procedure
    END pack1; -- end of package body
    /
show error
```
Invocation using SQL*Plus:
  VARIABLE c1 REFCURSOR
  EXEC scott.pack1.proc1 (:c1)
  PRINT c1

Invocation using SQL Passthru:
  SQL SQLORA EX scott.pack1.proc1
  TABLE FILE SQLOUT
  END

Example: An Oracle Stored Procedure Without REFCURSOR

The following Oracle stored procedure does not use REFCURSOR. It includes IN and OUT parameters.

sqlplus scott/tiger
set serveroutput ON

CREATE OR REPLACE PACKAGE pk1 AS
  PROCEDURE ibi_pr1 (v_num IN NUMBER,v_rec IN OUT VARCHAR2);
END;
/
sho error

CREATE OR REPLACE PACKAGE BODY pk1 AS
  PROCEDURE ibi_pr1 (v_num IN NUMBER,v_rec IN OUT VARCHAR2)
  IS
    v_msg    VARCHAR2(25);
    v_to_chr VARCHAR2(5);
  BEGIN
    v_to_chr := TO_CHAR(v_num);
    SELECT v_to_chr||' '||v_rec INTO v_msg FROM dual;
    v_rec := v_msg;
  END ibi_pr1;
END pk1;
/v
sho error
/*

Invocation using SQL*Plus:
    VARIABLE v_rec VARCHAR2(20)
    -- assign IN value to IN OUT parameter:
    -- BEGIN :v_rec := 'Your message!...'; END;
    BEGIN :v_rec := &1; END;
    /
    EXEC scott.pk1.ibi_pr1 (&2,:v_rec)
    PRINT v_rec
    --

Invocation using SQL Passthru:
    SQL SQLORA EX scott.pk1.ibi_pr1 12345, ?/'AbCdEf';
    END
*/
The Adapter for Oracle E-Business Suite is a read-only adapter providing security integration for reporting against Oracle E-Business Suite databases. This adapter supports user authentication and data access rules that are defined at the metadata and data access layer. Specific integrated data security is available for:

- Table and View Restrictions by Responsibility ID
- View Security by Set of Books ID
- View Security by Operating Unit

Using this adapter, you can access data with the following security models:

- Oracle Applications Security
- Union of Responsibilities Security
- Total Access Security

**Topics:**

- Preparing the Oracle E-Business Suite Environment
- Data Access and Security
- Configuring the Adapter for Oracle E-Business Suite
- Maintaining Security Rules
Preparing the Oracle E-Business Suite Environment

Before adding an Oracle E-Business Suite, you must prepare the environment. The preparation steps are:

- Configure the Adapter for Oracle.
- Generate any required synonyms in the Adapter for Oracle.
- Customize the General Ledger Security Package.

Configuring the Adapter for Oracle

The Adapter for Oracle is used to support connectivity to the Oracle E-Business Suite.

To add a connection to the Oracle database, follow the instructions in Configuring the Adapter for Oracle on page 1654. When defining a connection to the Oracle E-Business Suite database, you must use the delivered database APPS user ID and the connection name must be VIS.

The APPS user ID is the database ID, not an application user ID. Privileges assigned to the APPS user ID enable the enforcement of data security rules when accessing data. Functions performed by this ID include authentication, setting the application user system context, data selection, and accessing views with row-level data restrictions.

Note: For this purpose, Information Builders recommends that the Reporting Server be run in PTH security mode.

Creating Oracle Metadata

The Adapter for Oracle E-Business Suite uses synonyms that you create using the Adapter for Oracle. For details about creating these synonyms, see Managing Oracle Metadata on page 1661.
Customizing the General Ledger Security Package

How to:
Update the General Ledger Security Package

In order to execute views that contain calls to the Oracle E-Business Suite General Ledger Security Package (APPS.GL_SECURITY_PKG), the package must be customized to enable third party access. This package is called from within many General Ledger Business Views and performs the following functions:

- Updates temporary flex field tables.
- Uses the temporary tables in DDL of the views.

Procedure:  How to Update the General Ledger Security Package

To update the General Ledger Package:

1. Use the Oracle Enterprise Management Console (or equivalent) to locate the package body GL_SECURITY_PKG found in the APPS schema.
2. Select Edit, View to modify this package body.
3. Locate the following syntax in the init procedure:

   IF  (( instrb(program_name,'dis',-1,1) = 0 ) AND
   ( nvl(l_module,'XXX') <> 'Discoverer4' ) AND
   ( nvl(l_gl_bis_disco_flag,'N') <> 'Y' )
   THEN
   return;
   END IF;

   END IF;

4. Edit the syntax to include a new test on the program name, as follows:

   IF  (( instrb(program_name,'dis',-1,1) = 0 ) OR
   ( instrb(program_name,'tsc',-1,1) = 0 )) AND
   ( nvl(l_module,'XXX') <> 'Discoverer4' ) AND
   ( nvl(l_gl_bis_disco_flag,'N') <> 'Y' )
   THEN
   return;
   END IF;

This new syntax adds the tscom3.exe agent to the list of acceptable programs for the init procedure.
Data Access and Security

Reference: Data Access and Security Limitations

Oracle E-Business Suite relies on a combination of database functionality (views, stored procedures, and functions) along with interface rules to enforce business logic, such as data security rules. The adapter supports this design by enforcing security embedded rules within the database and by allowing queries to be written against both restricted and unrestricted types of data. Therefore, the adapter can be used to support data access with the following security models:

- **Oracle Applications Security.** Reports may be defined to require a Responsibility ID and Application ID as part of their processing. When this is done, requests against business views containing row-level security data restrictions will display the secured and filtered result data set only.

- **Union of Responsibilities.** When reporting against tables or views found in the applications, users will be able to access the full union of the data that all of their responsibilities allow. Only when Oracle Applications Security is defined will this data be further restricted to an individual responsibility ID access profile.

- **Total Enterprise Access.** Reports will always enforce table and view restrictions based on the application access granted to a given user. For all tables, and the subset of views that do not have row-level data security rules built-in, reports written against them will provide full data access.

Reference: Data Access and Security Limitations

- Synonyms created for use with this application adapter must be created with the same name as the underlying Oracle RDBMS Table or View.

- Oracle applications provide automated row-level security against many of the database views stored in its repository. These views are secured based on the initialization of environment settings during the user login process. The database tables do not support row-level security through this model automatically. To support row-level security against database tables, you must code filter criteria into individual reports.
Configuring the Adapter for Oracle E-Business Suite

**How to:**
- Configure the Adapter
- Create the Adapter Control Tables
- Configure the Remote Services Profile

**Example:**
- Sample edasprof.prf

The process of configuring the adapter includes configuring the adapter from either the Web Console or the Data Management Console, creating Oracle E-Business Suite control tables, and configuring the Remote Services Profile to call the adapter.

**Procedure: How to Configure the Adapter**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*
   or
   from the Data Management Console, expand the *Adapters* folder.
   The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the *ERP* group folder and the *Oracle Applications* folder.

4. Right-click *Oracle Applications* and select *Configure*.
   The Add Adapter to Configuration pane opens.

5. Accept the default configuration parameter:

   **Responsibility ID**
   Default value (-1) indicates that all individual Responsibility ID security rules will be combined. If another value were provided, only that specific Responsibility ID would be used for data access privileges.

6. Select a profile from the drop-down list to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default. For an illustration, see *Sample edasprof.prf* on page 1720.
If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down list and enter a name in the Profile Name input box. (The extension is added automatically.)

7. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Next step: When the configuration is complete, the next step is to create adapter control tables by running the oesfiles procedure. For details, see How to Create the Adapter Control Tables on page 1720.

Example: Sample edasprof.prf

```plaintext
- *
APP PATH OESSEC IBISAMP
- *
ENGINE SQLORA SET CONNECTION_ATTRIBUTES VIS VIS/apps,9AA42BAE9EC283A8
SET USER=ORAAPPS
ENGINE ORAAPPS SET APPS RESP_ID -1
```

Procedure: How to Create the Adapter Control Tables

You can create the adapter control tables from either the Web Console or the Data Management Console.

1. From the Web Console, select Applications

or

from the Data Management Console, right-click the server and select Connect.

2. In the navigation pane, expand the Application Directories folder, then expand the ibisamp folder.

3. From the list of procedures in ibisamp, right-click oesfiles and choose Run.

```
0 NUMBER OF RECORDS IN TABLE= 2546 LINES= 2546
ORAUSER.FOC: Oracle eBusiness Suite User Info
...Loaded
0 NUMBER OF RECORDS IN TABLE= 42094 LINES= 42094
ORASYSF.FOC: Oracle eBusiness Suite Table Info
...Loaded
```
Procedure: How to Configure the Remote Services Profile

1. Edit or create the Remote Service profile for the client node to be used for Oracle E-Business Suite data access. To do so, open the WebFOCUS Administration Console, navigate to the Reporting Servers Node, and select Profile from the options at the bottom of the page.
2. Add the _site_profile call to the adapter procedure, OESLOGIN.

`<VER1>`

```verbatim
# Site Profile: Adapter Oracle E-Business Suite
# Description: Enables remote user authentication against
# the Oracle E-Business Suite and passes necessary
# parameters to set the system context for the user
# Set default responsibility ID and application ID
# Calling application must set and validate the resp ID
# and appl ID before passing them to the procedure. If
# these are not validated they will still be passed, but
# invalid data may be returned for the user. If no values
# are set, these defaults will be used in setting the system
# context. In which case, certain database views will be
# unusable.
# Bind MR User to WF User
<ifdef> IBIMR_user
IBIC_user=&IBIMR_user
<endif>
<ifdef> IBIMR_pass
IBIC_pass=&IBIMR_pass
<endif>
# Responsibility ID (IBIWF_respid)
<ifndef> IBIWF_respid
IBIWF_respid=0
<endif>
# Application ID (IBIWF_applid)
<ifndef> IBIWF_applid
IBIWF_applid=0
<endif>

# Execute parameterized call to OESLOGIN
_site_profile=&_site_profile\EX OESLOGIN OES_RESP_ID=&IBIWF_respid,
_site_profile=&_site_profile\n OES_APPL_ID=&IBIWF_applid, PASSTHRU=ON
_site_profile=&_site_profile\n-RUN

# Enable these &variables to be passed to the server
<SET> IBIWF_respid(PASS)
<SET> IBIWF_applid(PASS)
```

### Maintaining Security Rules

The OESSEC application contains FOCUS tables loaded with security settings at a specific point in time. In order to maintain current data access security rules within these FOCUS tables, you must rerun the OESFILES procedure periodically. This procedure can be rerun manually, on an as-needed basis.
Alternatively, you can schedule the execution of OESFILES on a regular basis. Sites that use ReportCaster for scheduling can execute OESFILES as a Server Procedure Schedule Task. Sites that do not use ReportCaster can use any standard operating system scheduling tool.
Using the Adapter for parAccel

The Adapter for parAccel allows applications to access specific parAccel databases. The adapter converts application requests into parAccel calls and returns optimized answer sets to the requesting application.

Topics:
- Configuring the Adapter for parAccel
- Managing parAccel Metadata
Configuring the Adapter for parAccel

In this section:
Preparing the parAccel Environment
Declaring Connection Attributes
Overriding the Default Connection
Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Preparing the parAccel Environment

To use the Adapter for parAccel, you must first install the parAccel ODBC driver and all related libraries. To use this driver, you must configure a working data source using the ODBC Data Source Administrator. The Adapter will use this data source to access the parAccel database.

Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Example:
Declaring Connection Attributes

Reference:
Connection Attributes for parAccel

In order to connect to the parAccel database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).
Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one parAccel database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the parAccel server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

1. The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.
2. If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   
   or

   From the Data Management Console, expand the Adapters folder.
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.
**Reference:** Connection Attributes for parAccel

The parAccel adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**Datasource**

The data source name (DSN). There is no default data source name. You must enter a value.

This is the data source set in the ODBC Data Source Administrator.

**Security**

There are two methods by which a user can be authenticated when connecting to a data source:

- **Explicit.** The user ID and password are explicitly specified for each connection pass to the ODBC data source, at connection time, for authentication.

- **Trusted.** The adapter connects to the ODBC data source as a Windows login using the credentials of the operating system user impersonated by the server data access agent.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**File DSN parameters (optional)**

Is the path to the ODBC File DSN that is defined on your Windows machine or network.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).
**Syntax:**

**How to Declare Connection Attributes Manually**

For User/System DSN:

```
ENGINE SQLPARA SET CONNECTION_ATTRIBUTES connection
    DSNname/user_name,password,
```

For File DSN:

```
ENGINE SQLPARA SET CONNECTION_ATTRIBUTES connection
    FileDSN_name/,:'filedsn=FileDSN_path;','
```

where:

- **SQLPARA**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  
  Is the logical name used to identify this particular set of connection attributes.
  
  Note that one blank space is required between *connection* and *DSN_name*.

- **DSN_name**
  
  Is the parAccel Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

- **user_name**
  
  Is the primary authorization ID by which you are known to an parAccel data source.

- **password**
  
  Is the password associated with the primary authorization ID.

- **FileDSN_name**
  
  Is the name of parAccel File Data Source Name (DSN) you wish to access.

- **FileDSN_path**
  
  Is the path to the parAccel File DSN, which may reside on the hard drive or on the network.

**Example:**

**Declaring Connection Attributes**

For User/System DSN:

```
The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the parAccel DSN named SAMPLESERVER.

ENGINE SQLPARA SET CONNECTION_ATTRIBUTES CON1
    SAMPLESERVER/SAMPLEUSER,SAMPLEPASSWORD,
```

For File DSN:
The following SET CONNECTION_ATTRIBUTES command declares connection CON1 via the ODBC File DSN named SAMPLESERVER.dsn.

```
ENGINE SQLPARA SET CONNECTION_ATTRIBUTES CON2
SAMPLESERVER.dsn /,:'filedsn=C:\ SAMPLESERVER.dsn;'
```

**Overriding the Default Connection**

**How to:**

Change the Default Connection

**Example:**

Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:**

**How to Change the Default Connection**

```
ENGINE SQLPARA SET DEFAULT_CONNECTION connection
```

where:

- **SQLPARA**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  - Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

    `FOC1671, Command out of sequence`

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

    `FOC1671, Command out of sequence.`
**Example: Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```sql
ENGINE SQLPARA SET DEFAULT_CONNECTION SAMPLENAME
```

**Controlling the Connection Scope**

**How to:**

Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax: How to Control the Connection Scope**

```sql
ENGINE SQLPARA SET AUTODISCONNECT ON {FIN | COMMAND | COMMIT}
```

where:

**SQLPARA**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**FIN**

Disconnects automatically only after the session has been terminated. FIN is the default value.

**COMMAND**

Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

**COMMIT**

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing parAccel Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the parAccel data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLPARA to identify the Adapter for parAccel.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLPARA [,|$]
```

where:

`file`

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

`SQLPARA`

Is the value for the adapter.
Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Sample Generated Synonym

**Reference:**
Synonym Creation Parameters for parAccel
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each parAccel table or sheet that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   The *Select adapter to configure* or *Select connection to create synonym* pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.
   The Status pane indicates that the synonym was created successfully.
The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:** Synonym Creation Parameters for parAccel

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Note:** Due to internal settings of the parAccel, filtering by Owner/Schema might not be applicable to some database objects.
Location of External SQL Scripts

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed. During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

\[
\text{DATASET}=/ul/home2/apps/report3.sql
\]

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the Cardinality check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

With foreign key

Select the With foreign key check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

Dynamic columns

To specify that the Master File created for the synonym should not contain column information, select the Dynamic columns check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

For Subquery

Only available when External SQL Scripts is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.
Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Data Type Support on page 1739.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

❑ To select all tables in the list, click the Select All button.
❑ To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for parAccel synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.
Master File

FILENAME=ONHAND, SUFFIX=SQLPARA, $
SEGMENT=ONHAND, SEGTYPE=S0, $
   FIELDDNAME=PROD_NUM, ALIAS=Prod_Num, USAGE=A255V, ACTUAL=A255V, 
      MISSING=ON, $
   FIELDDNAME=PRODNAME, ALIAS=Prodname, USAGE=A255V, ACTUAL=A255V, 
      MISSING=ON, $
   FIELDDNAME=QTY_IN_STOCK, ALIAS=Qty_in_Stock, USAGE=D20.2, ACTUAL=D8, 
      MISSING=ON, $
   FIELDDNAME=PRICE, ALIAS=Price, USAGE=D20.2, ACTUAL=D8, 
      MISSING=ON, $
   FIELDDNAME=COST, ALIAS=Cost, USAGE=D20.2, ACTUAL=D8, 
      MISSING=ON, $

Access File

SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=DB1,KEYS=1,$

Reference:   Access File Keywords

This chart describes the keywords in the Access File for parAccel.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the parAccel table. The value assigned to this attribute can</td>
</tr>
<tr>
<td></td>
<td>include the name of the workbook as follows:</td>
</tr>
<tr>
<td></td>
<td>TABLENAME=[filename]table</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is:</td>
</tr>
<tr>
<td></td>
<td>CONNECTION=connection</td>

<tr>
<td></td>
<td>Absence of the CONNECTION attribute indicates access to the default</td>
</tr>
<tr>
<td></td>
<td>database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range</td>
</tr>
<tr>
<td></td>
<td>is 0 to 64. Corresponds to the first n fields in the Master File segment.</td>
</tr>
</tbody>
</table>
Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Data Type Support**

Data types are specific to the underlying data source.
The Adapter for PeopleSoft provides data access for reporting from the following PeopleSoft Record Types: SQL tables, SQL views, and query views. The adapter fully enforces PeopleSoft Query tree and row-level security.

The adapter provides three types of services:

- Authentication services.
- PeopleSoft data source connection management services.
- Metadata administration and data access security services.

**Topics:**

- Preparing the Environment
- Configuring the Adapter for PeopleSoft
- Managing PeopleSoft Metadata
- Managing PeopleSoft Secured Data Access
- Managing Connections to PeopleSoft
- Using Administrative Utilities
- Migrating from 7.1x and 7.6.x to 7.7
- Advanced Administrative Topics
Preparing the Environment

In this section:
Software Requirements
Setting Up the PeopleSoft Access ID

Prior to configuring the Adapter for PeopleSoft, you must ensure that minimal software requirements have been met. In addition, you must define a PeopleSoft Access ID to enforce PeopleSoft security. Administrators must also review available connection options before beginning the initial configuration.

Software Requirements

The following software is required on the server to support the Adapter for PeopleSoft:

- An appropriate RDBMS connectivity product on the computer where you will install the Adapter for PeopleSoft server. This is to provide access to a PeopleSoft data source server for operational data access.

- To support integrated authentication to PeopleSoft 8.1 or higher, Java 2 SDK version 1.3.1 or higher must be installed. Additionally, Publish and Subscribe services must be active on the PeopleSoft Application server.

  Note: For information about PeopleSoft with versions of software other than those listed in this topic, contact your Information Builders representative.

Setting Up the PeopleSoft Access ID

The Adapter for PeopleSoft initially authenticates with PeopleSoft using a PeopleSoft application user ID and password. If successful, the adapter attaches to the RDBMS using an access ID of your choice. Typically, this access ID is either the default PeopleSoft access ID (often it is SYSADM), or it is an RDBMS ID dedicated to the adapter. In either case, the access ID must have read access to the following PeopleSoft tables and views:

<table>
<thead>
<tr>
<th>PSCLASSDEFN</th>
<th>PSDBFIELD</th>
<th>PSDBFLDLABL</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSOPRCLS</td>
<td>PSOPRDEFN</td>
<td>PSOPTIONS</td>
</tr>
<tr>
<td>PSPRCSRQST</td>
<td>PSRECFIELDDB</td>
<td>PS_SCRTY_ACC_GRP</td>
</tr>
<tr>
<td>PS_TREE_ACCESS_VW</td>
<td>PSTREEDEFN</td>
<td>PSTREENODE</td>
</tr>
</tbody>
</table>
In addition, the access ID must have read access to any PeopleSoft Records that you wish to report against. If your PeopleSoft Records have row-level security, this ID must also have read access to the Query Security Records associated with each.

**Note:** The PSPRCSRQST and PSPRCSQUE tables are required only for Process Scheduler integration. If you are using this integration, these two files will also require write privileges.

### Configuring the Adapter for PeopleSoft

**In this section:**
- Adding the SQL Database Adapter
- Creating the SNAPCAT Application
- Configuring PeopleSoft Password Authentication
- Adding the First Connection to PeopleSoft

In order to configure PeopleSoft, you must add the underlying SQL adapter, create and register the PeopleSoft application (SNAPCAT) in the catalog path, add the first PeopleSoft connection, and, optionally, configure a JSCOM3 listener to ensure password authentication for PeopleSoft 8 and higher.

### Adding the SQL Database Adapter

**Example:**
- Adding an Oracle Adapter

The Adapter for PeopleSoft is an enhanced version of the underlying data source adapter. The adapter must be added into the server configuration.

When you add an SQL adapter, there is no need to provide configuration parameters since these connection parameters are stored in the server profile, which is accessible at all times to any user or application connecting to the server.

For most applications, the data access is then secured through procedure logic and operating system security. With PeopleSoft, this is not possible as there may be very large numbers of users who do not have operating system login IDs. Instead, these configuration parameters are supplied later when configuring connections to PeopleSoft data sources.

As a recommended practice when adding the new adapter, you may initially supply the configuration parameters, test data source connectivity, and then delete the connection statement in the server profile. While not required, when you attempt to create a connection to the PeopleSoft data source, this process may save significant time.
Example: Adding an Oracle Adapter
The Web Console provides graphical point and click tools to add and test the adapter.

1. From Web Console menu bar, click Adapters.
2. Expand the Available folder, if it is not already expanded.
3. Expand the SQL group folder and the Oracle folder.
4. Right-click a version and select Configure.
   The Add Adapter to Configuration pane opens.
5. Without supplying Oracle configuration parameters, click Configure.
   The Oracle adapter is added to your server configuration.
6. Optionally, test the connection if you provided temporary configuration parameters.

Creating the SNAPCAT Application

How to:
Create the SNAPCAT Application

Before you can configure the PeopleSoft adapter, the SNAPCAT application must be created and added to the application path of the server. This can be done through the Web Console.

Note: In the server release 7.7.04 and higher, it is no longer necessary to include the SNAPINST application directory in the application PATH. This directory is automatically added or removed from the PATH when needed.

Procedure: How to Create the SNAPCAT Application

1. From the Web Console menu bar, select Applications.
2. Right-click the Application Directories folder and select New, Application Directory.
The Create New Application window opens, as shown in the following image.

3. Change the Application Name to *snapcat*. Make sure it is all in lowercase.
4. Click OK.

**Configuring PeopleSoft Password Authentication**

**How to:**
Configure the JSCOM3 Listener

To leverage integrated authentication against PeopleSoft, a JSCOM3 listener must be configured using the Web Console. When completed, all user requests will pass calls to the PeopleSoft Component Interface architecture for authentication. If the configuration is either not using PeopleSoft or the connections are to be configured with TRUSTED authentication, then this step is not necessary.

**Note:** At this time, the PeopleSoft Component Interface does not support LDAP, even though the PeopleSoft Internet Architecture does read from LDAP repositories in general. This limitation means that if your PeopleSoft site uses LDAP integration for user authentication only, TRUSTED authentication is possible. To leverage your LDAP repository for WebFOCUS, use any of the standard integration methods available. For details, see the WebFOCUS Security and Administration manual.

Before configuring JSCOM3, the following conditions must be met:

- Ensure that the Publish and Subscribe services are running on the PeopleSoft Application Server. By turning these on, the jolt listener becomes active. Usually, these services are used for application messaging integration requirements, but the Adapter for PeopleSoft uses the same technology for authentication. No particular component interface must be accessible for the user to authenticate.
Several API files delivered with PeopleSoft must be made available to the Reporting Server directory. These files are located in the PeopleSoft file server libraries in the following locations:

- [PeopleSoft file server]\web\PSJOA\psjoa.jar
- [PeopleSoft file server]\web\jmac\pstools.properties

**Note:** With PeopleSoft 8.4 and higher, the pstools.properties file is no longer required.

If the Reporting Server is installed on the same computer as your PeopleSoft Application Server, then you may configure JSCOM3 to point directly to the files. Otherwise, the files must be copied to the computer with the Reporting Server. In this situation, it is recommended (but not required) that they be placed in your EDACONF\bin directory.

**Procedure:** How to Configure the JSCOM3 Listener

To configure the JSCOM3 listener:

1. From the Web Console menu bar, select **Workspace**.
2. From the navigation pane, expand the **Java Services** folder.
3. Right-click **DEFAULT**, and select **Properties**.
The Java Services Configuration pane opens.
4. Expand the Class path arrow.

5. Type the location of the psjoa.jar file in the IBI_CLASSPATH field, including the file name, for example, C:\Program Files\PeopleSoft\lib\psjoa.jar

Note: When upgrading the PeopleSoft Application Server after having performed these configuration steps, you must update the PeopleSoft files (psjoa.jar).

Adding the First Connection to PeopleSoft

How to:
Add the First PeopleSoft Connection

Reference:
Administration - Create a New PeopleSoft Connection Window
PeopleSoft Connection Worksheet

Although multiple PeopleSoft connections can be created, the first connection requires slightly different management steps. The reason for this is that before any connections to PeopleSoft data sources can occur, a base layer of application metadata is created and configured. This occurs transparently for the Administrator, but is a slightly different connection management process than when adding additional connections.
To create the first connection:

- Select and type a DBA password.
  
The DBA password is the value that is used as a metadata access key. To access the Web Console, the administrator must know this value. Users outside of the Web Console do not have metadata access without first logging in to PeopleSoft through this integration.

- Add a PeopleSoft Connection.

**Note:** In server release 7.7.04 and higher, it is no longer necessary to include PSLOGIN as a service profile.

**Procedure:** How to Add the First PeopleSoft Connection

1. Open the Web Console.
2. From Web Console menu bar, click *Adapters*.
3. Expand the *Available* folder, if it is not already expanded.
4. Expand the *ERP* group folder.
5. Right-click *Peoplesoft*, and select *Configure*.
6. Click *Configure*.
7. Click *Next*.

   The Administration - Create a DBA Password window opens.

8. In the *Enter DBA and Retype* fields, specify a DBA of up to eight characters, then click *Next*.

   The Administration - Create a New PeopleSoft Connection window opens.

9. Type the necessary information and click *Configure*.
10. Once the configuration finishes, click *Next*. 
Most of the parameters can be changed in the future, but the connection cannot be created without initially supplying correct data source connectivity information. For details on the required information, see Administration - Create a New PeopleSoft Connection Window on page 1751.

**Tip:** A worksheet is provided to assist you in gathering the information you will need to type on this screen. For details, see PeopleSoft Connection Worksheet on page 1755.

Processing may take several minutes to complete. Once completed, you may begin managing your new PeopleSoft Connection by adding synonyms and administering security access.
**Reference:** Administration - Create a New PeopleSoft Connection Window

The Administration - Create a New PeopleSoft Connection window contains the following fields/options:

**Description**

Is a description that identifies the current server configuration.
**PeopleTools Release**

Is the major PeopleSoft PeopleTools release number to access.

**Security Parameters**

**Security Enabled?**

Determines whether to enforce PeopleSoft data access security. The options are Yes and No. Yes is the default value.

**Specify Security Access By**

Determines the way in which the PeopleSoft administrator enables users to access the adapter and PeopleSoft data. The options are:

- **Class/Permission List.** Manages users in operating class (permission list) grouping.
- **User/Operation ID.** Manages users by individual user IDs.

**Connection Parameters**

**Database Type**

Is the Data source type. The options are: Oracle, MS SQL Server, and DB2 Universal Database.

**Database Identifier**

Is the data source identifier or system data source name.

If the server is co-located with the data residing in Oracle, do not type anything in the Database Identifier field.

**Server**

Name of the Database Server (for SQL Server only, not Oracle or DB2). If the instance of SQL Server you are configuring for is not running with the default port number, then the following syntax should be used:

```
nnn.nnn.nnn.nnn\instance_name, port
```

where

```
nnn.nnn.nnn.nnn
```

Is the IP address of the machine where SQL Server is running.

```
instance_name
```

Is the name of the SQL Server instance.

```
port
```

Is the listening port of the SQL Server instance.
Access ID

Is the RDBMS login ID for data source connectivity. Typically, it is the same login ID PeopleSoft uses to access the data source. There are minimum data access requirements that the ID must have. For details, see Setting Up the PeopleSoft Access ID on page 1742.

Access Password

Is a password associated with the access ID.

Database Owner

Is the data source owner identifier or the schema owner depending on your data source. The owner ID is used to fully qualify SQL requests passed to the data source. This allows multiple data source instances or schemas to exist in a single data source. Typical defaults are SYSADM on Oracle and dbo on Microsoft SQL Server.

Authentication Options

Authentication

Determines the authentication used in your application. The options are:

- **TRUSTED (Alternate Authentication).** Expects a valid pre-authenticated PeopleSoft user ID to be passed to the server to enable data access. This is useful with LDAP, Operating System security, or some other application that authenticates the user.

- **Password Required (Standard).** Expects a valid user ID and password before allowing data access. This is the default and is recommended for most environments.

Enforce Mixed Case IDs

Determines whether passwords are case-sensitive. Select Yes to enforce the PeopleSoft 8 use of mixed case user IDs or select No to revert to PeopleSoft 7.x case insensitivity.

If Password Required (Standard) is selected, two additional input fields are displayed:

Application Server

This is the IP address of the machine on which the JOLT Listener resides for the configured PeopleSoft environment.

JOLT Listener Port

Is the port number of the JOLT Listener.

Synonym Options

Default Synonym

Is the type of synonym to default to when creating new metadata. The options are: Record Name, Record Name with Prefix, Record Name with Suffix, Table Name, Table Name with Prefix, Table Name with Suffix.
**Note:** If you specify any of the options with Prefix or Suffix, the following additional input box is displayed.

### Prefix/Suffix Default

Enter the prefix or suffix you wish to prepend or append to the synonym name.

### Add Effective Date to synonyms

If this option is selected, additional field entries are added to any synonym created (or refreshed) after the configuration is saved. These new field entries provide the End Date of any row where an effective date field is part of the key. If an effective sequence is also part of the key, then the effective sequence field is also used in the calculation for the *End Date* field. In addition, filters are added to the synonym for the following:

- Current Record

and, if *Effective Sequence* field is present, the following filters are also added:

- First Effective Sequence
- Last Effective Sequence
- All Effective Sequences

These filters can be used in requests against the synonym and are available in the WebFOCUS reporting tool set.

To take advantage of this feature when migrating from an earlier release to release 7.7.02, first following the instructions in *Migrating from 7.1x and 7.6.x to 7.7* on page 1778, then edit each connection that needs this functionality, select the new option, and save the configuration. All synonyms should now be refreshed to have the new fields/filters added to them.

### Customize Synonym data type mapping

This option specifies how Long Character and CLOB data types in the PeopleSoft table should be reflected in the synonym.

#### Long Character Fields as

- **Fixed Length** – Any Long Character or CLOB will be converted to the Fixed Length value. In the following image, the synonym will have A500V for these two data types.
**Native Length** – Long Character fields will reflect the length as specified in the PeopleSoft table definition, CLOB will be converted to the Fixed Length value. In the following image, the synonym will have A500V for the CLOB data types.

Length or CLOB Length

**Length** – This is the length that will be used for both Long Character and CLOB fields if Fixed Length is selected.

**CLOB Length** – This is the length that will be used for all CLOB fields if Native Length is selected.

If this is a new connection configuration, all synonyms created after the configuration is saved will have these values. If an existing connection is being modified, synonyms will have to be refreshed to use these values.

**Reference: PeopleSoft Connection Worksheet**

Use the following worksheet to record connection configuration information and keep it for future reference.

<table>
<thead>
<tr>
<th><strong>Option Name</strong></th>
<th><strong>Response</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Row.</td>
<td>8-character identifier for linking metadata to PeopleSoft security rules. Must be consistent across multiple connections.</td>
</tr>
<tr>
<td>DBA</td>
<td></td>
<td>Major release of PeopleTools (8.1x, or 8.4x and above)</td>
</tr>
<tr>
<td>PeopleTools Release</td>
<td></td>
<td>Specifies whether PeopleSoft data security (row-level and access group) is enforced.</td>
</tr>
<tr>
<td>Security Enabled?</td>
<td></td>
<td>Specifies security access; by User (OPRID) or permission list (OPRCLASS).</td>
</tr>
<tr>
<td>Database Type</td>
<td></td>
<td>Designation for RDBMS. The options are Oracle, MS SQL Server, or DB2 Universal Database.</td>
</tr>
</tbody>
</table>
### Configuring the Adapter for PeopleSoft

<table>

Managing PeopleSoft Metadata

In this section:
- Accessing the Adapter for PeopleSoft Administrator
- Creating Synonyms
- Removing Synonyms
- Updating Synonyms
- Refreshing Synonyms
- Viewing Sample Data
- Renaming a Synonym

The Adapter for PeopleSoft enables management of PeopleSoft metadata. Processes exist that manage the accessibility of PeopleSoft Records by maintaining the metadata catalog on the reporting server. Before reports can be created or run, this metadata catalog must contain information about the PeopleSoft Record Definitions.

You can perform the following tasks to accomplish this:

- Create synonyms for PeopleSoft Records.
- Remove synonyms.
- Update synonyms.

Accessing the Adapter for PeopleSoft Administrator

How to:
Access the Adapter for PeopleSoft Administrator

To access the environment for administration, you must have access to the Web Console and knowledge of the DBA.

Procedure: How to Access the Adapter for PeopleSoft Administrator

1. Open the Web Console.
2. From Web Console menu bar, click Adapters.
3. In the navigation pane, right-click PeopleSoft from the list of configured adapters, and select Properties.
4. Type the DBA password, and click Next.

The PeopleSoft menu opens.

Creating Synonyms

How to:
Create Synonyms Using a Filtered Search
Create Synonyms Using a Query Tree Search

Creating synonyms for PeopleSoft is one of the core functions of the PeopleSoft Administrator. The adapter enables the administrator to choose which PeopleSoft records are defined in the metadata catalog.

The adapter provides two methods to select PeopleSoft Records to create synonyms:
Create synonyms using a filtered search. A search template option is provided to speed the process of searching for specific PeopleSoft Records. This is a useful method of locating Record Definitions when either the query tree location is not known or specific definitions that meet a filter can be more readily accessed.

Create synonyms using a query tree search. The query tree is a hierarchical logical grouping of the PeopleSoft Record Definitions. This method provides administrators familiar with this organizational structure a way to quickly locate related record definitions. Many sites create a combination query tree and access group definition specifically to group their records for use in reporting.

Procedure: How to Create Synonyms Using a Filtered Search

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.

2. Click Create under the Synonyms group.

   The Create Synonyms for Connection window opens.

3. Click Select PeopleSoft Records by Record Name and/or Description and type a Record name or description to filter by in the respective fields, or leave the fields blank to see a full list of Records.
Note:
- The Record Description is case-sensitive.
- If you do not use a filter, or your filtered results are very large, the results may be truncated. Use a different filter to reduce the returned results.

4. Click Next.
The Create Synonyms for Connection window opens.

5. Select the check box in the Create column for all the Records you want to create a synonym for, or select All to create a synonym for all available Records.

6. Optionally, change the synonym name in the Synonym name column.

7. Uncheck the Resynch Security File check box if you have more synonyms to create during this session. Leave it checked for the last Create Synonym run.

8. Click Create Synonym to process. Processing may take a few minutes for each selected Record Definition.
Procedure: How to Create Synonyms Using a Query Tree Search

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.

2. Click Create under the Synonyms group. The Create Synonyms for Connection window opens.

3. Click Select PeopleSoft Records by Query Tree/Access Group and click Next.

   The Create Synonyms - Select Query Tree for Connection window opens.

4. Select a Query Tree from the table by clicking the hyperlinked name.
The Create Synonyms - Select Access Group for Connection window reflects your selection.

5. In the Create Synonyms - Select Access Group for Connection window, click a hyperlinked name to drill down on an access group.
The Create Synonyms for Connection window opens.

6. Select the check box in the Create column for all the records you want to create a synonym for, or select All to create a synonym for all available records.

7. Optionally, change the synonym name in the Synonym name column.

8. Uncheck the Resynch Security File check box if you have more synonyms to create during this session. Leave it checked for the last Create Synonym run.

9. Click Create Synonym to process. Processing may take a few minutes for each selected record definition.

Removing Synonyms

**How to:**

Remove Synonyms

You can remove previously created PeopleSoft synonyms from the metadata catalog with the Remove Synonyms menu option.
Procedure: How to Remove Synonyms

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.

2. Click Remove under the Synonyms group.

   The Remove Synonyms for Connection window opens.

   ![Remove Synonyms for Connection](image)

   - **Remove**: AGING_CATEG_LG, AGING_CATEG_TBL, AGING_DETAIL, AGING_HEADER, AGING_TBL, AGING_TBL_LG, BD_ASSET, BD_ASSET_DEPR
   - **RECNNAME**: AGING_CATEG_LG, AGING_CATEG_TBL, AGING_DETAIL, AGING_HEADER, AGING_TBL, AGING_TBL_LG, BD_ASSET, BD_ASSET_DEPR
   - **SYNONYM**: AGING_CATEG_LG, AGING_CATEG_TBL, AGING_DETAIL, AGING_HEADER, AGING_TBL, AGING_TBL_LG, BD_ASSET, BD_ASSET_DEPR
   - **RECDSCR**: AGING_CATEG_LG, AGING_CATEG_TBL, AGING_DETAIL, AGING_HEADER, AGING_TBL, AGING_TBL_LG, Budgets Assets, Budgets Depreciation

3. Select the check box in the Remove column for each synonym you want to remove, or select All to remove all available synonyms.

4. Uncheck the Resynch Security File check box if you have more synonyms to remove during this session. Leave it checked for the last Remove Synonym run.

5. Click Remove Synonym.
Updating Synonyms

You can re-synchronize your metadata. This option:

- Queries the internal repository to determine which records were installed for the selected PeopleSoft connection.
- Compares the version number in those records with the version number in the PeopleSoft data source. If none of the records have changed, a message appears.

If there are any records that have changed, they appear in the Select Record(s) to Synchronize page.

**Procedure: How to Re-synchronize Synonyms**

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see *Accessing the Adapter for PeopleSoft Administrator* on page 1758.
2. Click Re-Synch under the Synonyms group.
   - The Synchronize Synonyms for Connection window opens.
3. Select the check box in the Synchronize column for each synonym you want to re-synchronize with PeopleSoft Record Definitions, or select All to re-synchronize all listed synonyms.
4. Click Synchronize Synonym.
Refreshing Synonyms

How to:
Refresh a Synonym

After creating your synonyms, you may need to fresh them at some point.

Procedure: How to Refresh a Synonym

1. From the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down menu. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.

2. Click Refresh under the Synonyms group.
   The Refresh Synonyms for Connection window opens.

3. Select the synonyms you want to fresh under the Refresh column, or select the All option.

4. Deselect the Resynch Security File check box if you have more synonym administration to do during this session. Leave it checked for the last synonym administration task.

5. Click Fresh Synonym.

Viewing Sample Data

After creating a synonym, you may want to verify that it is using the correct Record Definition. The Synonyms, View option on the PeopleSoft menu provides an easy method for listing the existing synonyms and viewing a sample data set from each.

Renaming a Synonym

You can selectively rename a synonym using the Synonyms, Edit option on the PeopleSoft menu.

After renaming a synonym, you must update references in existing reports from the old name to the new name using appropriate options in your reporting tool.
Managing PeopleSoft Secured Data Access

In this section:
- Enabling Access
- Disabling Access
- Updating Access

An administrator can manage security access according to individual users or a permission list. The decision for how to manage access is made as a connection option, and the two methods are mutually exclusive.

Regardless of the method for granting access rights to users, the process for managing security access is roughly identical. The administrator can affect security access for a user in the following ways:

- Adding security access.
- Removing security access.
- Resynchronizing security access.

Enabling Access

How to:
Enable Security Access

Before a PeopleSoft user can run reports against PeopleSoft, security access rights must be granted. The PeopleSoft connection does not automatically enable reporting for every user; instead an administrator must decide which users or permission lists have reporting access.
Note: Switching between users and permission lists is controlled by the Specify Security Access By drop-down menu under Security Parameters on the Update a PeopleSoft Connection window.

Procedure: How to Enable Security Access

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.

2. Click Add Access under the Security group.

   The Add Security Access to Connection window opens.

   ![Add Security Access to Connection window]

   Note: If the security parameter of your connection is set to Class/Permission Lists, the window will allow you to Select Permission Lists rather than Select Users.

3. Select filtering criteria to reduce the list of users or permission lists, and click Next, or leave the fields blank and click Next to see a full list.
Note: If you do not use a filter, or your filtered results are very large, the results may be truncated. Use a different filter to reduce the returned results.

The Add Security Access to Connection window opens.

4. Select the check boxes in the Add column for the users or permission lists you would like to add access for, or select All to add access for all those listed.

5. Click Add Users or Add Permission Lists to add your selections.

Note: When you add users by Permission List, the users will only be granted access to Records with which the added Permission Lists are associated.

Disabling Access

How to:
Remove Security Access

You can remove security access from the PeopleSoft menu.

Procedure: How to Remove Security Access

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.
2. Click *Remove Access* under the Security group.

The Remove Security for Connection window opens.

![Remove Security for Connection: E850A53](image)

**Note:** If the security parameter of your connection is set to *Class/Permission Lists*, the window will allow you to *Select Permission Lists* rather than *Select Users*.

3. Select the check boxes in the Remove column for the users or permission lists that should be removed, or select *All* to remove access for all those listed.

4. Click *Remove Users* or *Remove Permission Lists*.

The PeopleSoft connection removes all references to these users or permission lists. After they are removed, the associated users cannot access PeopleSoft data through the PeopleSoft adapter.

### Updating Access

**How to:**

Re-synchronize Security Rules

You can re-synchronize PeopleSoft security metadata when changes occur in the PeopleSoft environment. The following situations require resynchronization:

- A permission list has had query access group privileges modified.
- A Record has been added or removed from a query tree.
- A user has been added to or removed from a permission list with security access enabled.
- Row-level security class or permission lists are changed.
You do not need to run the security resynchronization routine if row-level security access has changed, based on the security table being updated. This type of security change will be enforced automatically and immediately. If the Query Security Record within a Record Definition has been changed, the synonym must be updated.

**Note:** A batch mechanism for resynchronization is also available that may be scheduled through a command line execution. For more information, see *Advanced Administrative Topics* on page 1779.

**Procedure:** How to Re-synchronize Security Rules

1. In the PeopleSoft menu, select the connection you want to manage from the **Select Connection** drop-down list. For details on accessing the PeopleSoft menu, see *Accessing the Adapter for PeopleSoft Administrator* on page 1758.

2. Click **Re-Synch** under the Security group. Security rules are re-synchronized based upon security access settings.

   Processing may take several minutes. Wait for a completion message before attempting other administrative tasks.

**Managing Connections to PeopleSoft**

<table>
<thead>

<tr>
<td>Adding a PeopleSoft Connection</td>
</tr>
<tr>
<td>Removing a PeopleSoft Connection</td>
</tr>
</tbody>
</table>

Multiple connections to PeopleSoft data sources are possible from within one server configuration. However, depending on your reporting requirements, it may be optimal to create separate configurations for each data source.

Creating multiple connections using the same server configuration is a good option under the following circumstances:

- The site has two or more PeopleSoft application suites and must perform significant combined reporting. A typical example is a site that has both PeopleSoft HRMS and PeopleSoft Financials applications where you must display data from both systems in a single report.

- Two or more PeopleSoft data sources that must be accessed reside on the same system. If the data sources must be accessed for display in a single report output and if the server is located on the same computer system, this architecture can provide optimal performance.
Two or more PeopleSoft data sources reside in different locations with requirements for moderate to significant consolidated reporting. This architecture provides optimal effectiveness in report development, system maintenance, and performance.

Create separate configurations instead of using multiple connections in these situations:

- Only a single PeopleSoft production data source must be supported. Each development and test instance should have a separate configuration.
- Multiple PeopleSoft data sources exist with only a limited requirement for combining data in reports.

The remaining instructions in this topic assume a single configuration directory structure for one or more data source connections.

### Updating a PeopleSoft Connection

**How to:**

Edit a PeopleSoft Connection

**Reference:**

Updating Connections

If it becomes necessary to update the connection parameters to a PeopleSoft data source, you can use Administration options to perform the following functions:

- Turn PeopleSoft data access security enforcement on or off.
- Toggle between trusted and password authentication.
- Manage the user access specification type.
- Manage all data source identification information.
- Define default synonym behavior.

**Procedure:** How to Edit a PeopleSoft Connection

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.
2. Click Connections under the Administration group.
The Administration - Maintain Connections window opens.

3. Select Update Existing.

4. Select a connection from the Select PeopleSoft Connection drop-down list.

5. Click Next.

   The Administration - Update a PeopleSoft Connection window opens. For details, see Administration - Create a New PeopleSoft Connection Window on page 1751.

6. Make the modifications you wish, and click Continue.

7. On the next screen, click Next.

**Reference: Updating Connections**

When you change the Specify Security Access By setting, you must re-synchronize security before changes will take effect. We suggest that you remove all currently configured users before you make this change, and re-add them after security settings have been modified.

As when you modify authentication information, you must be careful to manage changes to data source connectivity correctly. Always modify your settings in the PeopleSoft Connection first, then change them at the data source. Where possible, keep both access options in place during a configuration conversion process until tests have verified a successful switch.
Adding a PeopleSoft Connection

**How to:**
Add a PeopleSoft Data Source Instance

After you add your first connection, you can specify additional PeopleSoft connections. Note that during this process, you are not prompted for the DBA information prior to managing metadata and connection information since all additional PeopleSoft data sources must use the same DBA in order for base metadata to function properly.

**Procedure: How to Add a PeopleSoft Data Source Instance**

1. In the PeopleSoft menu, select the connection you want to manage from the **Select Connection** drop-down list. For details on accessing the PeopleSoft menu, see *Accessing the Adapter for PeopleSoft Administrator* on page 1758.

2. Click **Connections** under the **Administration** group.

   The Administration - Maintain Connections window opens.

3. Select **Add New**.

   **Note:** If there are currently no connections, **Add** will be the only option.

4. Click **Next**.

   The Administration - Create a New PeopleSoft Connection window opens. For details, see *Administration - Create a New PeopleSoft Connection Window* on page 1751.

5. Type the necessary information and click **Configure**.

6. On the next screen, click **Next**.

   When processing finishes, you can manage your synonyms and security for this connection.

Removing a PeopleSoft Connection

**How to:**
Remove a PeopleSoft Connection

The integration with PeopleSoft depends on valid connection information. If a previously created connection is no longer required, you should remove that connection.
Procedure: How to Remove a PeopleSoft Connection

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.

2. Click Connections under the Administration group.
   The Administration - Maintain Connections window opens.

3. Select a connection from the Select Connection drop-down list.

4. Select Remove Existing.

5. Click Next.
   The Administration - Remove a PeopleSoft Connection window opens.
   You are prompted to confirm. After confirmation, the system removes the selected PeopleSoft Connection and all of its associated metadata.

Using Administrative Utilities

In this section:
Connection Reports
Updating the DBA Password
Tracing Adapter Processing
Log off

The Adapter for PeopleSoft provides administrative tools that enable you to report on connection information, update the DBA Password, and set adapter tracing options.

Connection Reports

How to:
Run Connection Reports

The Administrator provides reports to make administration easier. You can run reports that provide information on connections, metadata, users, and user access. These reports are accessible from the index.
**Procedure: How to Run Connection Reports**

1. In the PeopleSoft menu, select the connection you want to manage from the Select Connection drop-down list. For details on accessing the PeopleSoft menu, see Accessing the Adapter for PeopleSoft Administrator on page 1758.

2. Click Reports under the Administration group.

   The Administration - Reports window opens.

   ![Administration - Reports](image)

3. If necessary, select the PeopleSoft connection you want to run a report for from the PeopleSoft Connection drop-down list.

4. Select a report type from the Administration Report drop-down list. The options are:
   - **Connection Information.** Retrieves statistics for your connection.
   - **Synonyms.** Retrieves a list of available synonyms.
   - **Users/Oprids.** Retrieves a list of users who have access to the current connection.
   - **Access Assigned.** Retrieves a list of the access assigned to each user.

5. Select an output format for the report from the Output Format drop-down list. The options are HTML and PDF.

6. Click Run.

   The selected report appears.

**Updating the DBA Password**

The DBA Password option is used for updating the password that is supplied during the initial configuration of the adapter. When the password is updated, all synonyms are updated as well. (Note that this process may take several minutes.)
Tracing Adapter Processing

The adapter tracing utility creates application level traces for support purposes. Typically, tracing is used under the direction of Information Builders Customer Support Services.

Log off

This option, when clicked, will provide a confirmation dialog box to log off from the adapter and free the server agent. Select OK or Cancel.

Note: Closing the window will have the same effect (without the confirmation box).

Migrating from 7.1x and 7.6.x to 7.7

After installing the 7.7 server, follow these steps for migrating the PeopleSoft Adapter environment from 7.1.x or 7.6.x releases.

1. Create the following three directories under the 7.7 server’s approot directory.
   - snapcat
   - snapcat/bak
   - snapinst

2. Copy the contents of the old snapinst and snapcat folders to the new directories.

3. Update the Application Path to include snapcat.

4. Configure the relevant SQL Database Adapter.

5. Configure the PeopleSoft Adapter.

6. Proceed to Adding the First Connection to PeopleSoft on the DBA screen, and enter the DBA password that you used in the earlier release.

The PeopleSoft adapter is now ready for use.

Note: If you are migrating from a server release earlier than 7.7.04 to release 7.7.04 (or later), the PSLOGIN procedure will be added to each synonym, as an MFD_PROFILE entry, that is registered to the PeopleSoft adapter. This process will take place every time the adapter is used via the Web Console. Existing synonyms will be backed up in application directory SNAPBAK and a log file will be created in the same directory. The log file name takes the format: psmiglog_hh.mm.ss and will be created every time that the adapter is used.

Note: If you wish to migrate from a 5.3 release, please contact Information Builders Customer Support Service (CSS) at (800) 736-6130 or (212) 736-6130 for instructions.
Advanced Administrative Topics

In this section:
Automating Security Access Updates
Troubleshooting Tips

In addition to the standard administrative options described in this chapter, advanced options and techniques are available to assist in automating security access updates and troubleshooting integration problems. This topic discusses these options and provides additional details on PeopleSoft security integration.

Automating Security Access Updates

How to:
Use the PeopleSoft Interactive Agent
Run Batch Mode Security Resynchronization From the Command Line
Capture Execution Results

Example:
Creating a Custom Server Startup Script for UNIX
Capturing Execution Results

Reference:
Password Security

Security resynchronization is one of the functions of the PeopleSoft Administrator. When administering PeopleSoft connections through the Web console, you simply select the Re-Synch link under the Security group, and all of the PeopleSoft data security rules are resynchronized.

The batch resynchronization utility enables administrators to schedule, through an operating system command, the execution of this functionality without having to manually open the Administrator tool. By scheduling this process nightly (or otherwise; based on business requirements), administrators are not required to perform this function manually, and they can be assured that the data security rules are current as of the last scheduled run.

The utility is comprised of two files. These files are a procedure (pssecsnk.fex) used in executing the resynchronization routine and a t3i script (pssecsnk.t3i), which is the command line input file. By starting the server with the t3i script as an input, the server performs the required security resynchronization without user intervention.
A server can be accessed locally without the use of client software. This functionality can be started in the following two modes:

- **Interactive Agent** is useful for:
  - Debugging application errors.
  - Troubleshooting connectivity and configuration.
  - Testing performance.

- **Batch Mode** is useful for scheduling batch scripts with operating system tools.

An administrative user with access to the server can use the server in stand-alone mode to perform any of these functions. If PeopleSoft data must be accessed in any of these processes, you must execute the PeopleSoft authentication routine. Because of the processing within the authentication routine, the creation of a custom startup script is recommended.

The two purposes for the custom script are:

- To enable successful execution of the PSLOGIN remote procedure call.
- To ensure that when executing, a separate and temporary workspace is used. This prevents errors due to concurrent processing, including data access errors.

When using the edastart script, temporary files are always written to the current directory. When using edastart without modification, be sure to delete these temporary files from the current directory after execution to avoid unexpected results during run time.

**Example:**  **Creating a Custom Server Startup Script for UNIX**

The following provides the steps for creating and using a custom startup script in UNIX.

Navigate to the EDACONF/bin directory on your server and create a new script with a text editor. The following script is named pslocal. The numbers on the left correspond to the notes explaining the code.
Note: This example creates a unique directory under the $EDACONF/edalocal directory. The edalocal directory must exist in most operating systems before a directory can be created within it.

```bash
#!/bin/ksh
#
parms=$*
#
# Define the Conf Directory
1. export EDACONF=/ibi/srv77/wfs
   #
   #  Create unique temporary directory for running locally
2. EDA_PID=&&
   export EDATEMP=$EDACONF/edalocal/$EDA_PID
   rm -rf $EDATEMP
   mkdir $EDATEMP
3. cd $EDATEMP
4. $EDACONF/bin/edastart $parms
5. cd $EDACONF/bin
     rm -r $EDATEMP
```

The script processes as follows:

1. The export command defines the EDACONF variable to use. This makes the remainder of the script more flexible and portable.
2. These four lines define a unique directory based on a PID and UNIX process ID so that all temporary files will be written to a unique location.
3. The CD command changes the current directory to the new temporary directory.
4. This line calls the delivered edastart script and parameters passed through the script.
5. These two lines change the current directory from the temporary space, and deletes the temporary files.

The following is an example of a script similar to the UNIX version but for Windows.

```bash
@ECHO ON
setlocal
set EDATEMP=c:\ibi\srv77\wfs
echo %EDATEMP%
mkdir %EDATEMP%\edalocal
cd %EDATEMP%\edalocal
%EDATEMP%\bin\edastart %*
endlocal
```

**Procedure:** How to Use the PeopleSoft Interactive Agent

The following procedure is for a UNIX environment.
1. Navigate to the server configuration directory, then to the bin subdirectory.

2. Execute the Interactive Agent start-up script with the -t option. This is the same for UNIX and Windows platforms

   `/ibi/srv77/wfs/bin/pslocal -t`

   where:

   `/ibi/srv77/wfs/bin`

   Is the bin directory under the server configuration.

   When you run

   `pslocal -t`

   you see information similar to:

   ```
   RELEASE = R727704B
   GEN_NUM = 624
   BUILD_DATE = 09/26/2011 20:06:57
   INSTALLATION_DATE = 9/26/2011 20:32:17
   >>
   ```

   At the prompt, you can type commands.

3. To perform any commands that access PeopleSoft data, first you must run the interactive authentication routine. If this procedure is not run, you receive data access errors. To execute the procedure, type

   ```
   >>EX PSLOGIN USERID=PS_Userid, PASSWD=PS_Password
   ```

   where:

   `PS_Userid` and `PS_Password`

   Is a valid PeopleSoft user ID and password.

   You see processing information followed by a FOCUS command prompt. After control returns to the FOCUS command prompt, PeopleSoft data may be accessed with the FOCUS language.

   **Note:** If your configuration has been set up with Trusted authentication, then you are not required to supply the PeopleSoft password. Only a valid user ID is required.

**Procedure: How to Run Batch Mode Security Resynchronization From the Command Line**

The following procedure is for a Windows environment.

1. Locate the pssecsnk.t3i script in the EDACONF\catalog directory.
2. Using PeopleSoft Batch-Mode, execute with the security synchronization input script. To execute input scripts with the pslocal script, use the -f option

    c:\ibi\srv77\wfs\bin\pslocal -f c:\ibi\srv77\wfs\catalog\pssecsnk.t3i

where:

    c:\ibi\srv77\wfs\catalog

Is the directory location of the t3i file.

For details about securing the script, see Password Security on page 1783.

Reference: Password Security

The t3i script is an ASCII text file that must be edited for your particular environment. It contains two FOCUS execute command lines that:

- Log into PeopleSoft.
- Perform the security resynchronization.

The syntax is:

```
< Filename: pssecsnk.t3i >
%CONNECT
%BEGIN
EX PSLOGIN USERID=PS, PASSWD=PS, PSBATCH=X
EX PSSECBAT
%END
%DISCONNECT
%STOP_SERVER
```

You must modify the user ID and password in accordance with one that is appropriate for your environment. The user ID must be granted access in PeopleSoft.

Since the file is in readable text, the administrator must prevent read/write access for anyone not authorized to access the t3i. The best way to prevent unauthorized access is to use operating system security. Windows and UNIX provide ways to prevent unauthorized access to individual files and entire directories. Contact your operating system administrator for assistance in performing this security step.

Procedure: How to Capture Execution Results

Usually, after execution, all temporary work files are deleted immediately. If you must verify work files or see the batch process output file, you can temporarily modify the execution script.
To temporarily prevent the deletion of these processing files, edit the pslocal script found in the EDACONF/bin directory. Insert the appropriate comment character for your environment where the final file deletion step exists.

In UNIX environments, type:

```bash
# rm -r $EDATEMP
```

After the script has been executed, the Administrator can review the execution results. A batch process output file (pssecsnk.t3o) is automatically created in the EDACONF/edalocal directory, with a unique subdirectory for each execution.

For an illustration, see *Creating a Custom Server Startup Script for UNIX* on page 1780.

**Example:** Capturing Execution Results

The following is an example of a successful execution:

```bash
< Filename: pssecsnk.t3o >
%connect
%begin
ex pslogin userid=ps, passwd=ps
ex pssecbat
%end
SYSPRINT.SCR
0 NUMBER OF RECORDS IN TABLE=       1  LINES=      1
File doesn't exist
Successful Security Re-synch for Connection: E850A53
   DBNUM: 1 has been re-synchronized, DBA security is: ON
CLOSEALL.ALL
%disconnect
%stop_server
```

**Note:** As the user ID and password appear in this output file, the file must be protected by operating system security.

**Troubleshooting Tips**

**How to:**

Connect to the PeopleSoft Data Sources

Verify Security

These troubleshooting tips help if you are getting FOCUS error messages, such as a FOC1302, or if you are seeing SQL errors when you run reports.
**Procedure: How to Connect to the PeopleSoft Data Sources**

The most likely source of difficulty in connecting to your PeopleSoft data source is the data source connectivity. If you are experiencing difficulty connecting to the data source:

1. Verify that the data source instance is up and running.
2. Run a client query tool on the server, using the PeopleSoft access ID.
   - If you cannot log in to the data source, there is a problem with the access ID.
     - Verify the ID and check to see if the password has changed.
     - If the password has changed, then it must also be changed in the PeopleSoft configuration.
   - If you can log in, proceed to Step 3.
3. Run a few simple queries against the PeopleSoft records that are returning errors.
   - If you are not getting any rows back, check to see if the PeopleSoft access ID has read authority on the PeopleSoft records you are accessing.

**Procedure: How to Verify Security**

PeopleSoft enforces all the security mechanisms used by the PeopleSoft Query tool. This includes Query Tree security and row-level security. If you are getting unexpected results, it is possible that your PeopleSoft security has not been configured properly.

To verify that security is being properly enforced:

1. Verify that the synonym(s) being queried are correct.
   - The Administrator can run a report of installed records to verify. If row-level security is the issue, the server-side ACX file should be reviewed and compared to the record definition in PeopleSoft, including the Security Search record.
2. Create a similar query in PS/Query. The SQL code can be viewed and compared to SQL tracing on the server.
3. Examine the SQL.
   - Does it appear to match the business logic behind the original request? If not, check the syntax behind the original FOCUS code. Perhaps you are using a WRITE instead of a PRINT, or perhaps a WHERE clause has been coded incorrectly.
4. Run this SQL directly against the RDBMS using a data source query tool.
If you are getting the expected results, then there may be a problem with the program logic after the data is returned to FOCUS from the RDBMS. Examine COMPUTE/DEFINE statements for logic errors or, if you are using ON TABLE HOLD, there may be a problem in your code.

If you are getting the same unexpected results, then examine the underlying data. Perhaps some cross-referenced fields are missing, or perhaps row-level security is eliminating essential rows.
The Adapter for PostgreSQL allows applications to access PostgreSQL data sources. The adapter converts application requests into PostgreSQL calls and returns optimized answer sets to the requesting application.

Topics:
- Preparing the PostgreSQL Environment
- Configuring the Adapter for PostgreSQL
- Managing PostgreSQL Metadata
- Customizing the PostgreSQL Environment
- Optimization Settings
Preparing the PostgreSQL Environment

How to:  
Set Up the Environment on Windows and UNIX

In order to use the Adapter for PostgreSQL, you must install the PostgreSQL driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure:  
How to Set Up the Environment on Windows and UNIX

1. Identify the location of the PostgreSQL Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX or IBM i location for some JDBC Driver files to /
   /usr/driver_files/mydriver.jar, issue the commands:

   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH

   Similarly, on Windows, you would issue the command:

   set CLASSPATH=c:\usr\driver_files\mydriver.jar;%CLASSPATH%

   Note that if you run the server workspace as a Windows service, you must set the
   CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the
   CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server
   workspace

   edastart -show

   and check the special services section displays "JSCOM3 active".

   If the JSCOM3 service is not active, a "fail to start" message will typically also be in
   the server EDAPRINT log. To resolve the problem, review the JDBC listener requirements in
   the chapter for your operating system in the Server Installation manual.
Configuring the Adapter for PostgreSQL

In this section:
Declaring Connection Attributes
Overriding the Default Connection
Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Example:
Declaring Connection Attributes

Reference:
Connection Attributes for PostgreSQL

In order to connect to a PostgreSQL data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf), if supported on your platform.

You can declare connections to more than one PostgreSQL data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.
**Procedure:** **How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*.
   
or
   From the Data Management Console, expand the *Adapters* folder.
   The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

**Reference:** **Connection Attributes for PostgreSQL**

The *PostgreSQL* adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**URL**

Location URL for the PostgreSQL data source.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**Driver name**

Name for the PostgreSQL JDBC driver.
For example: org.postgresql.Driver

See PostgreSQL documentation for the specific driver release you are using.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax: How to Declare Connection Attributes Manually**

```plaintext
ENGINE SQLPSTGR SET CONNECTION_ATTRIBUTES connection
'URL'/userid,password
```

where:

- **SQLPSTGR**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  - Is the connection name.

- **URL**
  - Is the URL to the location of the PostgreSQL data source.

- **userid**
  - Is the primary authorization ID by which you are known to the target database.

- **password**
  - Is the password associated with the primary authorization ID.

**Example: Declaring Connection Attributes**

The following SET CONNECTION_ATTRIBUTES command connects to a data source using the PostgreSQL Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMS will encrypt the password before adding it to the server profile.
Note: Consult vendor documentation for the exact name, port, and path.

ENGINE SQLPSTGR SET CONNECTION_ATTRIBUTES CON1 'jdbc:postgresql://hostname:5432/qatst'

Overriding the Default Connection

<table>
<thead>
<tr>
<th>How to:</th>
<th>Change the Default Connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Selecting the Default Connection</td>
</tr>
</tbody>
</table>

If multiple connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

ENGINE SQLPSTGR SET DEFAULT_CONNECTION connection

where:

SQLPSTGR
- Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection
- Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

FOC1671, Command out of sequence

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

FOC1671, Command out of sequence.
**Example: Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```
ENGINE SQLPSTGR SET DEFAULT_CONNECTION SAMPLENAME
```

**Controlling the Connection Scope**

**How to:**

Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:**

**How to Control the Connection Scope**

```
ENGINE SQLPSTGR SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

- **SQLPSTGR**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **FIN**
  - Disconnects automatically only after the session has been terminated. FIN is the default value.

- **COMMIT**
  - Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing PostgreSQL Metadata

In this section:
Identifying the Adapter
Accessing Database Tables
Creating Synonyms
Data Type Support
Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

**Identifying the Adapter**

**How to:**
Identify the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLPSTGR to identify the Adapter for PostgreSQL.

**Syntax:**

```
FILE(NAME)= file, SUFFIX=SQLPSTGR [, $]
```

where:

- **file**
  - Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

- **SQLPSTGR**
  - Is the value for the adapter.

**Accessing Database Tables**

If you choose to access a remote third-party table using PostgreSQL, you must locally install the RDBMS PostgreSQL Driver.
The Server can access third-party database tables across the PostgreSQL network. You must specify a URL for the data source and, possibly, a user ID and/or password for the database you are accessing. You can define these parameters in either the server global profile or in a user profile.

Creating Synonyms

How to:
Create a Synonym

Example:
Sample Generated Synonym

Reference:
Synonym Creation Parameters for PostgreSQL
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source's location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server's metadata.

Note: If you are creating a synonym for a PostgreSQL data source, you must first add the syntax SET SYNONYM=BASIC to the edasprof.prf file.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:**  **Synonym Creation Parameters for PostgreSQL**

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
Object name. Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the Base Location field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the Document Name field, enter the file name with or without wild card characters.
- In the Document Extension field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the Base Location field, enter:
  
  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The Document Extension is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the Cardinality check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
**With foreign key**

Select the *With foreign key* check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Customize data type mappings**

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support* on page 1802.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

**Example:** Sample Generated Synonym

An Adapter for PostgreSQL synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

**Master File nf29004.mas**

FILE=DIVISION, SUFFIX=SQLPSTGR ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$

**Access File nf29004.acx**

SEGNAME=SEG1_4, TABLENAME=EDAQA.NF29004,
CONNECTION=CON1, KEYS=1, WRITE=YES,$

**Reference:** Access File Keywords

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the PostgreSQL table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: &lt;br&gt;TABLENAME=[owner.]table</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is: &lt;br&gt;CONNECTION=connection &lt;br&gt;CONNECTION=' ' indicates access to the local data source. &lt;br&gt;Absence of the CONNECTION attribute indicates access to the default database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first n fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>KEYFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td>IXFLD</td>
<td>❑ KEYFLD is the FIELDNAME of the common column from the parent table. &lt;br&gt;❑ IXFLD is the FIELDNAME of the common column from the related table. &lt;br&gt;KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. &lt;br&gt;&lt;strong&gt;Note:&lt;/strong&gt; An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.</td>
</tr>
</tbody>
</table>
Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. Note: To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. Note: This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
### Data Management

Followed by these options, if applicable:

- **Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)

- **Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted.

- **Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values.

- **Reorganize.** Recreates the data source table preserving original data.

**Note:** This option is not available in the Web Console.

### Impact Analysis

Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.

### Copy

Copies the synonym to the clipboard.

### Delete

Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.

### Cut

Deletes the synonym and places it on the clipboard.

### Properties

Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

### Data Type Support

The following table lists how the server maps PostgreSQL data types. Note that you can change the precision and scale of numeric columns. For information, see *Changing the Precision and Scale of Numeric Columns* on page 1805.

Be sure to review those options carefully as they affect the mapping of data types.
<table>
<thead>
<tr>
<th>Name</th>

</tbody>
</table>

**POSTGIS data type.** In addition to the data types listed above, the Adapter for PostgreSQL supports the PostGIS POINT(XY) data type. This data type is used to describe geographical data. The adapter is able to connect to PostGIS databases, create PostGIS tables, and use PostGIS POINT(X,Y) data with READ/WRITE functionality.

POINT fields are mapped in synonyms as A42. Please note that other PostGIS data types (such as line, circle, box, lseg, path and polygon) have not been certified.
Changing the Precision and Scale of Numeric Columns

How to:

Override the Default Precision and Scale

Example:

Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

Syntax: How to Override the Default Precision and Scale

ENGINE SQLPSTGR SET CONVERSION RESET
ENGINE SQLPSTGR SET CONVERSION format RESET
ENGINE SQLPSTGR SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLPSTGR SET CONVERSION format [PRECISION MAX]

where:

SQLPSTGR

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

RESET

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

format

Is any valid format supported by the data source. Possible values are:

INTEGER which indicates that the command applies only to INTEGER columns.

DECIMAL which indicates that the command applies only to DECIMAL columns.

REAL which indicates that the command applies only to single-precision floating-point columns.

Note: Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```bash
ENGINE SQLPSTGR SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```bash
ENGINE SQLPSTGR SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```bash
ENGINE SQLPSTGR SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```bash
ENGINE SQLPSTGR SET CONVERSION RESET
```

---

**Customizing the PostgreSQL Environment**

**In this section:**
- Specifying a Timeout Limit
- Cancelling Long Requests
- Obtaining the Number of Rows Updated or Deleted

The Adapter for PostgreSQL provides several parameters for customizing the environment and optimizing performance.

**Specifying a Timeout Limit**

**How to:**

Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to PostgreSQL.

**Syntax:** How to Issue the TIMEOUT Command

```bash
ENGINE SQLPSTGR SET TIMEOUT \{nn|0\}
```
Customizing the PostgreSQL Environment

where:

SQLPSTGR

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a time-out occurs. 30 is the default value.

0

Represents an infinite period to wait for a response.

Cancelling Long Requests

**How to:**

Cancel Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

**Procedure:** How to Cancel Long Requests

1. From the Web Console menu bar choose Workspace, Configuration/Monitor, Java Services, DEFAULT. Right-click on DEFAULT and select Agents.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select Stop.

Obtaining the Number of Rows Updated or Deleted

**How to:**

Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
**Syntax:** How to Obtain the Number of Rows Updated or Deleted

```sql
ENGINE SQLPSTGR SET PASSRECS {ON|OFF}
```

where:

- **SQLPSTGR**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **ON**
  - Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

- **OFF**
  - Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

**Optimization Settings**

**In this section:**
- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

How to:
Optimize Requests

Example:
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

Reference:
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

```
SQL SQLPSTGR SET {OPTIMIZATION|SQLJOIN} setting
```

where:

SQLPSTGR

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

SQLJOIN

Is a synonym for OPTIMIZATION.

setting

Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:**  SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLPSTGR SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
FOR FETCH ONLY;
```

**Example:**  SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLPSTGR SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.EMPINFO T1,'USER1'.FUNDTRAN T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID, T1.LN
ORDER BY T2.EID, T1.LN;
```

**Reference:** SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:** Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**
- Using IF-THEN_ELSE Optimization Without Aggregation
- Using IF-THEN_ELSE Optimization With Aggregation
- Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:** SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.
**Syntax:** How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLPSTGR SET OPTIFTHENELSE {ON | OFF}
```

where:

**SQLPSTGR**

Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Enables IF-THEN-ELSE optimization. This is the default.

**OFF**

Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
SQL SQLPSTGR SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = ' ') AND (T1.'FN' = ' ')
AND (T1.'DPT' = 'MIS'))));
```
**Example:** Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
SQL SQLPSTGR SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
   WHERE (((T1.'LN' = 'SMITH')));
```

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
   WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

**Example:** Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```sql
SQL SQLPSTGR SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
**Reference: SQL Limitations on Optimization of DEFINE Expressions**

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  
  \[ X = X + 1; \]

- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX and MIN prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

**Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
The Adapter for Progress allows applications to access Progress data sources. The adapter converts application requests into native Progress statements and returns optimized answer sets to the requesting application.

**Topics:**
- Preparing the Progress Environment
- Configuring the Adapter for Progress
- Managing Progress Metadata
- Customizing the Progress Environment
- Optimization Settings
Preparing the Progress Environment

How to:
- Set Up the Environment on Windows Using ODBC
- Set Up the Environment on UNIX Using ODBC

Currently, the Progress environment is supported on UNIX and Windows. The Adapter for Progress is available as an ODBC interface.

Procedure: How to Set Up the Environment on Windows Using ODBC
On Windows, the Progress environment is set up during the installation of the product.

Procedure: How to Set Up the Environment on UNIX Using ODBC
1. Specify the full name of the directory containing Progress.
   
   \texttt{DLC=/rdbms/pro91d/dlc}

2. Specify the full name of the default Progress startup file.
   
   \texttt{PROSTARTUP=/rdbms/pro91d/dlc/startupyy.pf}

3. Specify the location of the ODBC initialization file.
   
   \texttt{ODBCINI=/usr/odbc/ibiodbc/progress.ini}

4. Specify the path to the Progress shared libraries.
   
   \texttt{LIBPATH=/rdbms/pro91d/dlc/odbc/lib:/rdbms/pro91d/dlc/lib}

Configuring the Adapter for Progress

In this section:
- Connecting to a Progress Database Server
- Declaring Connection Attributes
- Overriding the Default Connection
- Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Connecting to a Progress Database Server

For an ODBC interface, the server must be brought up in TCP/IP mode.

Declaring Connection Attributes

**How to:**
Declare Connection Attributes
Declare Connection Attributes Manually

**Example:**
Declaring Connection Attributes

**Reference:**
Connection Attributes for Progress Using ODBC
Updating the Connection String

In order to connect to a Progress database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one Progress database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the Progress Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.
Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   
   or
   
   From the Data Management Console, expand the Adapters folder.
   
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for Progress Using ODBC

The Progress adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource

The data source name (DSN). There is no default data source name. You must enter a value.

User

Authorization ID to connect to the source.

Password

Password associated with the authorization ID.
Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

**ENGINE SQLPRO SET CONNECTION_ATTRIBUTES connection DSN_name/.userid,password**

where:

**SQLPRO**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**

Is the logical name used to identify this particular set of connection attributes. Note that one blank space is required between connection and DSN_name.

**DSN_name**

Is the Progress Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

**userid**

Is the primary authorization ID by which you are known to Progress.

**password**

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the Progress DSN named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

**ENGINE SQLPRO SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS**
**Reference: Updating the Connection String**

The syntax for the CONNNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Web Console Migrate option migrates your server settings to the newer release. To access this option, select *Workspace*, then *Configuration/Monitor* from the menu bar. Right-click *Migrate* from the *Server* folder in the navigation pane, and select *Configure*. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the *Migrate* button. This is the recommended approach.

If you choose *not* to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.

- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.

- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=*

For example, suppose that prior to Version 7 Release 6.1, the connection was defined as:

```
ENGINE SQLPRO SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
```

When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

```
CONNECTION=DSN_A
```

If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

```
ENGINE SQLPRO SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
```
Overriding the Default Connection

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:**

**How to Change the Default Connection**

ENGINE SQLPRO SET DEFAULT_CONNECTION connection

where:

**SQLPRO**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

FOC1671, Command out of sequence

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

FOC1671, Command out of sequence.

**Example:**

Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

ENGINE SQLPRO SET DEFAULT_CONNECTION SAMPLENAME
Controlling the Connection Scope

**How to:**
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:**

`ENGINE SQLPRO SET AUTODISCONNECT ON {FIN | COMMAND | COMMIT}`

where:

**SQLPRO**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**FIN**
Disconnects automatically only after the session has been terminated. FIN is the default value.

**COMMAND**
Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

**COMMIT**
Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing Progress Metadata

In this section:
Creating Synonyms
Progress Data Type Support
Controlling the Mapping of Large Character Data Types for SQL-92
Controlling the Mapping of Variable-Length Data Types for SQL-92
Trailing Blanks in SQL Expressions
Changing the Precision and Scale of Numeric Columns
Manipulating Arrays Created in the 4GL Environment Under SQL-92

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Progress data types.

Creating Synonyms

How to:
Create a Synonym

Example:
Sample Generated Synonym

Reference:
Synonym Creation Parameters for Progress
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each Progress table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.
Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

Reference: Synonym Creation Parameters for Progress

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters ("," or "/") and comments.
Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Location of External SQL Scripts**

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the **Base Location** field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the **Document Name** field, enter the file name with or without wild card characters.

- In the **Document Extension** field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the **Base Location** field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The **Document Extension** is understood to be MBR. You can enter this value explicitly or leave the input box blank.
During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

**With foreign key**

Select the *With foreign key* check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.
Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Progress Data Type Support on page 1833.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

☐ To select all tables in the list, click the Select All button.

☐ To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Progress synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.
**Generated Master File nf29004.mas**

```plaintext
FILE=DIVISION, SUFFIX=SQLPRO ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON ,$
```

**Generated Access File nf29004.acx**

```plaintext
SEGNAME=SEG1_4 ,TABLENAME=EDAQA.NF29004,
KEYS=1, WRITE=YES ,$
```

**Reference:** Access File Keywords

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Name of the table or view. This value can include a location or owner name as follows: TABLENAME=[location.][owner.]tablename</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is: CONNECTION=connection</td>
</tr>
<tr>
<td></td>
<td>CONNECTION='' indicates access to the local database server. Absence of the CONNECTION attribute indicates access to the default database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first n fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
</tbody>
</table>
Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.

- KEYFLD is the FIELDNAME of the common column from the parent table.
- IXFLD is the FIELDNAME of the common column from the related table.

KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.

**Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

<table>
<thead>
<tr>
<th>Description</th>
<th>Description</th>

<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the <em>Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS</em> manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

<td><strong>ARRAY</strong></td>
<td>AV</td>
</tr>
</tbody>
</table>

The following table lists how the server maps Character data types. This mapping can be changed based on the value of LONGCHAR. The default value is ALPHA.
### Controlling the Mapping of Large Character Data Types for SQL-92

**How to:**

Control the Mapping of Large Character Data Types

The SET parameter CONVERSION LONGCHAR controls the mapping of supported Progress data types listed below. By default, the server maps these data types as alphanumeric (A). The server data type A supports a maximum of 4096 characters for TABLE/MODIFY and 32768 characters for API applications.

The following table lists data type mappings based on the value of LONGCHAR:

<table>
<thead>
<tr>
<th>Progress Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>$n$ is an integer between 1 and 2000</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td></td>
<td>$n$ is an integer between 257 and 2000</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>$n$ is an integer between 1 and 256</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td></td>
<td>$n$ is an integer between 257 and 4000</td>
<td>AnV</td>
<td>AnV</td>
</tr>
</tbody>
</table>

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.
Syntax: How to Control the Mapping of Large Character Data Types

```
ENGINE SQLPRO SET CONVERSION LONGCHAR {ALPHA|TEXT|BLOB}
```

where:

**SQLPRO**
- Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ALPHA**
- Maps the Progress data types CHAR and VARCHAR as alphanumeric (A). ALPHA is the default value.

**TEXT**
- Maps the Progress data types CHAR and VARCHAR as text (TX). Use this value for WebFOCUS applications.

**BLOB**
- For UNIX and Windows, is identical to ALPHA. That is, it maps the Progress data types CHAR and VARCHAR as alphanumeric (A).
Controlling the Mapping of Variable-Length Data Types for SQL-92

How to:  
Control the Mapping of Variable-Length Data Types

The SET parameter VARCHAR controls the mapping of the Progress data type VARCHAR. By default, the server maps these data types as variable character (AnV).

The following table lists data type mappings based on the value of VARCHAR:

<table>
<thead>
<tr>
<th>Progress Data Type</th>
<th>Remarks</th>
<th>VARCHAR ON</th>
<th>VARCHAR OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR (n)</td>
<td>n is an integer between 1 and 4000</td>
<td>AnV</td>
<td>An</td>
</tr>
</tbody>
</table>

Syntax:  
How to Control the Mapping of Variable-Length Data Types

ENGINE SQLPRO SET VARCHAR {ON|OFF}

where:

SQLPRO
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON
  Maps the Progress data type VARCHAR as variable-length alphanumeric (AnV). ON is the default value.

OFF
  Maps the Progress data type VARCHAR as alphanumeric (A).

Trailing Blanks in SQL Expressions

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

ENGINE SQLPRO SET TRIM_LITERALS ON

is available to ensure backward compatibility.
Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

```sql
ENGINE SQLPRO SET CONVERSION RESET
ENGINE SQLPRO SET CONVERSION format RESET
ENGINE SQLPRO SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLPRO SET CONVERSION format [PRECISION MAX]
```

where:

**SQLPRO**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**

Is any valid format supported by the data source. Possible values are:

- **INTEGER** which indicates that the command applies only to INTEGER columns.
- **DECIMAL** which indicates that the command applies only to DECIMAL columns.
- **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of **MAX**).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```
ENGINE SQLPRO SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```
ENGINE SQLPRO SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```
ENGINE SQLPRO SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```
ENGINE SQLPRO SET CONVERSION RESET
```

**Manipulating Arrays Created in the 4GL Environment Under SQL-92**

**Example:** Sample Master File With Arrays

When the Adapter for Progress creates a synonym from an array in the Progress 4GL environment, the array values are translated into a semi-colon delimited list. This is dictated by limitations on array support by the Progress client API for both metadata and processing.

**Example:** Sample Master File With Arrays

In this example the ARRAY column is called ITEMS. The metadata generated by the Adapter for Progress (under SQL-92/ODBC) represents ITEMS using the data type VARCHAR. The Adapter for Progress queries the Progress field SQL_WIDTH (which sets field widths to twice the length of the displayed format) in order to determine the USAGE and ACTUAL fields lengths in the synonym.

One additional step is required to retrieve data from the values in the synonym: you must manipulate the array using the WebFOCUS function GETTOK, which divides a character string into substrings (called tokens). A specific character, called a delimiter, occurs in the string and separates it into tokens. GETTOK returns the token specified by the token_number. For example, to extract the second value from five defined in an array, you would specify 2 as the token_number and the semi-colon character as the delimiter. GETTOK would then divide the string into substrings using this delimiter and extract the second value.
Following is a synonym containing the array field ITEMS followed by a two procedures: the first produces a semi-colon delimited list; the second uses the GETTOK function to retrieves data from the array field.

**Synonym**

FILENAME=ARRAYTAB, SUFFIX=SQLPRO , $
SEGMENT=ARRAYTAB, SEGTYPE=S0, $
  FIELDNAME=CUSTOMER, ALIAS=customer, USAGE=A40V, ACTUAL=A40V, MISSING=ON, $
  FIELDNAME=ITEMS, ALIAS=items, USAGE=A60V, ACTUAL=A60V, MISSING=ON, $

**Basic Procedure**

Since the concept of an array, with five distinct items (item1=val1; item2=val2; etc.) does not exist for Progress in the SQL-92 environment, the item values for customer 1 are represented as a semi-colon delimited list.

```
TABLE FILE ARRAYTAB
PRINT *
END
```

The output is:

```
CUSTOMER                  ITEMS
--------                  -----
customer1                val1;val2;val3;val4;val5
```

**Procedure With GETTOK**

In this procedure, the GETTOK function is used to retrieve a single value from the array

```
TABLE FILE ARRAYTAB
PRINT CUSTOMER AND COMPUTE
ARRAY/A5 = GETTOK(ITEMS, 60, 2, ';', 5, ARRAY);
END
```

where the function arguments are:

<table>
<thead>
<tr>
<th>GETTOK argument value</th>
<th>Is...</th>
</tr>
</thead>
<tbody>
<tr>
<td>ITEMS</td>
<td>A field in the synonym.</td>
</tr>
<tr>
<td>60</td>
<td>The length of the ITEMS field.</td>
</tr>
<tr>
<td>2</td>
<td>The number of the token (value) to extract from the array.</td>
</tr>
</tbody>
</table>
Customizing the Progress Environment

<table>
<thead>
<tr>
<th>GETTOK argument value</th>
<th>Is...</th>
</tr>
</thead>
<tbody>
<tr>
<td>;</td>
<td>The delimiter character enclosed in single quotation marks (which must be a semi-colon in this context).</td>
</tr>
<tr>
<td>5</td>
<td>The maximum length of the field (in this example, it must match the length of ARRAY/A5).</td>
</tr>
<tr>
<td>ARRAY</td>
<td>The field in which to store the generated output.</td>
</tr>
</tbody>
</table>

The output is:

CUSTOMER          ARRAY
--------          -----  
customer1         val2

For details about the GETTOK function, see the *WebFOCUS Using Functions* manual.

Customizing the Progress Environment

**In this section:**
- Activating NONBLOCK Mode
- Obtaining the Number of Rows Updated or Deleted
- Specifying a Time-out Limit
- Specifying the Transaction Isolation Level

The Adapter for Progress provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.

**Activating NONBLOCK Mode**

**How to:**

Activate NONBLOCK Mode

The Adapter for Progress has the ability to issue calls in NONBLOCK mode. The default behavior is BLOCK mode.

This feature allows the adapter to react to a client request to cancel a query while the adapter is waiting on engine processing. This wait state usually occurs during SQL parsing, before the first row of an answer set is ready for delivery to the adapter or while waiting for access to an object that has been locked by another application.
**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax:**

**How to Activate NONBLOCK Mode**

ENGINE SQLPRO SET NONBLOCK {0|n}

where:

SQLPRO

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n

Is a positive numeric number. 0 is the default value, which means that the adapter will operate in BLOCK mode. A value of 1 or greater activates the NONBLOCK calling and specifies the time, in seconds, that the adapter will wait between each time it checks to see if the:

- Query has been executed.
- Client application has requested the cancellation of a query.
- Kill Session button on the Web Console is pressed.

**Note:** A value of 1 or 2 should be sufficient for normal operations.

**Obtaining the Number of Rows Updated or Deleted**

**How to:**

Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax:**

**How to Obtain the Number of Rows Updated or Deleted**

ENGINE SQLPRO SET PASSRECS {ON|OFF}
where:

SQLPRO
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON
Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF
Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

**Specifying a Time-out Limit**

**How to:**
Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to Progress.

**Syntax:**

How to Issue the TIMEOUT Command

ENGINE SQLPRO SET TIMEOUT \{nn|0\}

where:

SQLPRO
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn
Is the number of seconds before a time-out occurs. 30 is the default value.

0
Represents an infinite period to wait for a response.
Specifying the Transaction Isolation Level

How to: Specify Transaction Isolation Level From a SET Command

You can specify the transaction isolation level from the Web Console or using the SET ISOLATION command.

Syntax: How to Specify Transaction Isolation Level From a SET Command

You can specify transaction isolation level by issuing the following command

\[
\text{ENGINE SQLPro SET ISOLATION \{RU|RC|RR|SE\}}
\]

where:

RU

Sets the transaction isolation level to Read Uncommitted.

RC

Sets the transaction isolation level to Read Committed.

RR

Sets the transaction isolation level to Repeatable Read.

SE

Sets the transaction isolation level to Serializable Read.

Optimization Settings

In this section:

- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields
- Optimizing Requests to Pass Virtual Fields Defined as Constants
- Specifying Block Size for Retrieval Processing

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

How to: Optimize Requests

Example: SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

Reference: SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

```
SQL SQLPRO SET {OPTIMIZATION|SQLJOIN} setting
```

where:

SQLPRO

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

SQLJOIN

Is a synonym for OPTIMIZATION.

setting

Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:** SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLPRO SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
```

```
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
  FOR FETCH ONLY;
```

**Example:** SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLPRO SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

AGGREGATION DONE ...

    SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
    FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
    WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
    GROUP BY T2.EID, T1.LN
    ORDER BY T2.EID, T1.LN;

**Reference:** SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:**

Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**

Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**

SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.
Syntax: How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

SQL SQLPRO SET OPTIFTHENELSE {ON|OFF}

where:

SQLPRO
Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

ON
Enables IF-THEN-ELSE optimization. This is the default.

OFF
Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

Example: Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

SQL SQLPRO SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = '') AND (T1.'FN' = ' ') AND (T1.'DPT' = 'MIS')));
**Example: Using IF-THEN_ELSE Optimization With Aggregation**

Consider the following request:

```sql
SQL SQLPRO SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
   ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
   WHERE (((T1.'LN' = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
   WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

**Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False**

```sql
SQL SQLPRO SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END
```

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
Reference: SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  \[ X = X + 1; \]
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX and MIN prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

**Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Optimizing Requests to Pass Virtual Fields Defined as Constants

A virtual field defined as a constant is passed directly to an SQL database engine (RDBMS) for optimized processing that takes advantage of RDBMS join, sort, and aggregation capabilities, thus reducing the volume of RDBMS-to-server communication and improving response time. (In prior releases, constants were not passed to the database engine, causing optimization to be turned off.)

Constants in the following formats are passed to the RDBMS: NUMERIC, CHAR, VARCHAR, CHAR/INTEGER combination, and DATE. (Note that a few formats are not passed to the RDBMS. These are CHAR and VARCHAR combination, TIME, and DATETIME.)

When valid constants are passed to an RDBMS engine, a report is calculated based on the defined value(s) and only the calculated subset of records is returned. The extent of data manipulation at the adapter level is limited, thereby improving performance.

**Example: Passing Numeric Constants**

```focuser
DEFINE FILE SMIX87
INTEGERCONST/I4 = 5
REALCONST/D20.2 = -97995.38
NUMERICCONST/P13.4 = -92999.3647

TABLE FILE SMIX87
  SUM INTEGERCONST REALCONST NUMERICCONST MAX.QUOT.FA01INTEGER
  BY QUOT.FA02INTEGER
END
```

The following SQL is generated:

```sql
SELECT T2."FA02INTEGER", SUM(5), SUM(-97995.38),
  SUM(-92999.3647), MAX(T2."FA01INTEGER") FROM TMIX83A T2 GROUP
  BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Example: Passing a CHAR Constant**

```focuser
DEFINE FILE SMIX87
CHARCONST/A10 = '2N'
```
The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), MIN(T3."FA02CHAR_15") FROM TMIX83A T2, TMIX86A T3 WHERE (T3."FA01INTEGER" = T2."FA01INTEGER") GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Example:** Passing CHAR and INTEGER Constants

```sql
DEFINE FILE SMIX87
CHARCONST/A10 = '2N'
INTEGERCONST/I4 = 5

TABLE FILE SMIX87
SUM CHARCONST INTEGERCONST
BY QUOT.FA02INTEGER
END
```

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), SUM(5) FROM TMIX83A T2
GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Specifying Block Size for Retrieval Processing**

**How to:**
Specify Block Size for Insert Processing

The Adapter for Progress supports array retrieval from result sets produced by executing SELECT queries or stored procedures. This technique substantially reduces network traffic and CPU utilization.

Using high values increases the efficiency of requests involving many rows, at the cost of higher virtual storage requirements. A value higher than 100 is not recommended because the increased efficiency it would provide is generally negligible.

**Tip:** You can change this setting manually or from the Web Console by clicking Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the right-click menu. The Change Settings pane opens.
**Syntax:**  
**How to Specify Block Size for Insert Processing**

In combination with LOADONLY, the block size for an INSERT applies to MODIFY INCLUDE requests. INSERTSIZE is also supported for parameterized DIRECT SQL INSERT statements.

```
ENGINE SQLPRO SET INSERTSIZE n
```

where:

- **SQLPRO**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **n**
  
  Is the number of rows to be inserted using array insert techniques. Accepted values are 1 to 5000. 1 is the default value. If the result set contains a column that has to be processed as a BLOB, the INSERTSIZE value used for that result set is 1.
The Adapter for PSQL allows applications to access PSQL data sources. The adapter converts application requests into PSQL calls and returns optimized answer sets to the requesting application.

**Topics:**
- Preparing the PSQL Environment
- Configuring the Adapter for PSQL
- Managing PSQL Metadata
- Customizing the PSQL Environment
- Optimization Settings
Preparing the PSQL Environment

How to: Set Up the Environment on Windows and UNIX

In order to use the Adapter for PSQL, you must install the PSQL driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the PSQL Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX or IBM i location for some JDBC Driver files to /usr/driver_files/mydriver.jar, issue the commands:

   `CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH`  
   `export CLASSPATH`

   Similarly, on Windows, you would issue the command:

   `set CLASSPATH=c:\usr\driver_files\mydriver.jar;%CLASSPATH%`

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace

   `edastart -show`

   and check the special services section displays "JSCOM3 active".

   If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server’s EDAPRINT. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the Server Installation manual.
Configuring the Adapter for PSQL

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

In order to connect to a PSQL data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one PSQL data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.
**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*.
   
   or

   From the Data Management Console, expand the *Adapters* folder.
   
   The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.
   
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

**Reference: Connection Attributes for PSQL**

The PSQL adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

- **Connection name**
  
  Logical name used to identify this particular set of connection attributes. The default is CON01.

- **URL**
  
  Location URL for the PSQL data source.

- **User**
  
  Primary authorization ID by which you are known to the data source.

- **Password**
  
  Password associated with the primary authorization ID.

- **Driver name**
  
  Name for the PSQL JDBC driver.
See PSQL documentation for the specific driver release you are using.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:**  
How to Declare Connection Attributes Manually

```sql
ENGINE SQLPSQ SET CONNECTION_ATTRIBUTES connection 'URL'/userid,password
```

where:

- **SQLPSQ**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  - Is the connection name.

- **URL**
  - Is the URL to the location of the PSQL data source.

- **userid**
  - Is the primary authorization ID by which you are known to the target database.

- **password**
  - Is the password associated with the primary authorization ID.

**Example:**  
Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to a books data source using the PSQL Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

**Note:** Consult your vendor documentation for the exact name, port, and path.

```sql
ENGINE SQLPSQ SET CONNECTION_ATTRIBUTES CON1 'jdbc:pervasive://edared30:1583/DEMODATA
```
Overriding the Default Connection

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

If multiple connections have been defined, the connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

**Syntax:**

```plaintext
ENGINE SQLPSQ SET DEFAULT_CONNECTION connection
```

where:

- **SQLPSQ**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

  `FOC1671, Command out of sequence`

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  `FOC1671, Command out of sequence`.

**Example:**

Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```plaintext
ENGINE SQLPSQ SET DEFAULT_CONNECTION SAMPLENAME
```
Controlling the Connection Scope

How to: Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

ENGINE SQLPSQ SET AUTODISCONNECT ON {FIN | COMMIT}

where:

SQLPSQ  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN  Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMIT  Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing PSQL Metadata

In this section:

- Identifying the Adapter
- Accessing Database Tables
- Creating Synonyms
- Data Type Support
- Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.
Identifying the Adapter

How to: Identify the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLPSQ to identify the Adapter for PSQL.

Syntax: How to Identify the Adapter

FILE[NAME]=file, SUFFIX=SQLPSQ [,$]

where:

file

Is the file name for the Master File. The file name without the .mas extension can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLPSQ

Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using PSQL, you must locally install the RDBMS PSQL Driver.

The Server can access third-party database tables across the PSQL network. You must specify a URL for the data source and, possibly, a user ID and/or password for the database you are accessing. You can define these parameters in either the server global profile or in a user profile.
Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Sample Generated Synonym

**Reference:**
Synonym Creation Parameters for PSQL
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

**Note:** If you are creating a synonym for a PSQL data source, you must first add the syntax SET SYNONYM=BASIC to the edasprof.prf file.

**Procedure:** How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   The Applications page opens.
2. Click the *New* button and select *Synonym* from the drop-down menu.
   The *Select adapter to configure* or *Select connection to create synonym* pane opens.
3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.
4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.
5. After entering the parameter values, click Create Synonym.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

Reference: Synonym Creation Parameters for PSQL

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters ("," or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- Owner/Schema. Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
Object name. Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the Base Location field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the Document Name field, enter the file name with or without wildcard characters.

- In the Document Extension field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the Base Location field, enter:

  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE

- The Document Extension is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the Cardinality check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
**With foreign key**

Select the *With foreign key* check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Customize data type mappings**

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support* on page 1870.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Owner/Schema**

The user account that created the object or a collection of objects owned by a user.

**Type**

The object type (Table, View, and so on).

**Select tables**

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the **Select All** button.
- To select specific tables, select the corresponding check boxes.

**Example: Sample Generated Synonym**

An Adapter for PSQL synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

**Master File nf29004.mas**

```
FILE=DIVISION, SUFFIX=SQLPSQ ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$
```

**Access File nf29004.acx**

```
SEGNAME=SEG1_4, TABLENAME=EDAQA.NF29004,
CONNECTION=CON1, KEYS=1, WRITE=YES,$
```

**Reference: Access File Keywords**

This chart describes keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td><strong>Keyword</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| TABLENAME  | Identifies the PSQL table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows:  
\[
\text{TABLENAME}=[\text{owner.}]\text{table}
\] |
| CONNECTION | Indicates a previously declared connection. The syntax is:  
\[
\text{CONNECTION}=\text{connection}
\]  
\[
\text{CONNECTION}='\ ' \text{indicates access to the local data source.}
\]  
Absence of the CONNECTION attribute indicates access to the default database server. |
| KEYS       | Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first \( n \) fields in the Master File segment. |
| WRITE      | Specifies whether write operations are allowed against the table. |
| KEYFLD     | Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.  
- KEYFLD is the FIELDNAME of the common column from the parent table.  
- IXFLD is the FIELDNAME of the common column from the related table.  
KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.  
**Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently. |
Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
<td></td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
<td></td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Data Type Support**

Data types are specific to the underlying data source.
Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**
How to Override the Default Precision and Scale

```
ENGINE SQLPSQ SET CONVERSION RESET
ENGINE SQLPSQ SET CONVERSION format RESET
ENGINE SQLPSQ SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLPSQ SET CONVERSION format [PRECISION MAX]
```

where:

**SQLPSQ**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**
Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**
Is any valid format supported by the data source. Possible values are:

- **INTEGER** which indicates that the command applies only to INTEGER columns.
- **DECIMAL** which indicates that the command applies only to DECIMAL columns.
- **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```sql
ENGINE SQLPSQ SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```sql
ENGINE SQLPSQ SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```sql
ENGINE SQLPSQ SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```sql
ENGINE SQLPSQ SET CONVERSION RESET
```

**Customizing the PSQL Environment**

The Adapter for PSQL provides several parameters for customizing the environment and optimizing performance.

### In this section:
- Specifying a Timeout Limit
- Cancelling Long Requests
- Obtaining the Number of Rows Updated or Deleted

**Specifying a Timeout Limit**

**How to:**

Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to PSQL.

**Syntax:**

**How to Issue the TIMEOUT Command**

```sql
ENGINE SQLPSQ SET TIMEOUT \{nn\}0
```
where:

SQLPSQ

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a timeout occurs. 30 is the default value.

0

Represents an infinite period to wait for a response.

Cancelling Long Requests

**How to:**
Cancel Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

**Procedure:**  **How to Cancel Long Requests**

1. From the Web Console menu bar choose Workspace, Configuration/Monitor, Java Services, DEFAULT. Right-click on DEFAULT and select Agents.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select Stop.

Obtaining the Number of Rows Updated or Deleted

**How to:**
Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
**Syntax:**

*How to Obtain the Number of Rows Updated or Deleted*

ENGINE SQLPSQ SET PASSRECS {ON|OFF}

where:

**SQLPSQ**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

**OFF**

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

---

**Optimization Settings**

**In this section:**

- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

How to:
Optimize Requests

Example:
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

Reference:
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax:  

How to Optimize Requests

SQL SQLPSQ SET {OPTIMIZATION|SQLJOIN} setting

where:

SQLPSQ
Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

SQLJOIN
Is a synonym for OPTIMIZATION.

setting
Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:** SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (\?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLPSQ SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
FOR FETCH ONLY;
```

**Example:** SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLPSQ SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

AGGREGATION DONE ...

    SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
    FROM 'USER1'. 'EMPINFO' T1,'USER1'. 'FUNDTRAN' T2
    WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
    GROUP BY T2.EID, T1.LN
    ORDER BY T2.EID, T1.LN;

Reference: SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

How to:
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

Example:
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

Reference:
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
Syntax: How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```
SQL SQLPSQ SET OPTIFTHENELSE {ON | OFF}
```

where:

**SQLPSQ**
Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**
Enables IF-THEN-ELSE optimization. This is the default.

**OFF**
Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

Example: Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```
SQL SQLPSQ SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```
SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = ' ') AND (T1.'FN' = ' '))
     AND (T1.'DPT' = 'MIS'))
```
Example: Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
SQL SQLPSQ SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
   WHERE (((T1.'LN' = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
   WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```sql
SQL SQLPSQ SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  \[ X = X + 1; \]
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

**Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Optimization Settings
The Adapter for Query/400 enables you to create synonyms that WebFOCUS can use for reporting against a Query/400 query definition.

The adapter generates metadata from an existing Query/400 object in such a way that only the required fields and ancillary information is retained for use as a basis for requests or queries.

This Adapter for Query/400 is intended to be used in conjunction with the Web Query client product.
Preparing the Adapter for Query/400 Environment

The Adapter for Query/400 does not require setting any environment variables. However, any query definitions for which you wish to create synonyms must already be available to the adapter. You cannot use the adapter to create these definitions.

Configuring the Adapter for Query/400

**How to:**
Configure the Adapter for Query/400

You can configure the Adapter for Query/400 from the Web Console or from the Data Management Console.

**Procedure:** How to Configure the Adapter for Query/400

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*.
   
or
   From the Data Management Console, expand the *Adapters* folder.
   
The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.
   
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

**Note:** The Query/400 adapter is under the *Procedures* group folder. No input parameters are required.
Managing Query/400 Metadata

In this section:
Creating Synonyms

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of an existing Query/400 request and its underlying tables, columns, and associated data types.

Creating Synonyms

How to:
Create a Synonym

Example:
Creating a Synonym for Query/400

Reference:
Synonym Creation Parameters for Query/400
Managing Synonyms

Synonyms define unique names (or aliases) for each Query/400 request that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.

The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:** **Synonym Creation Parameters for Query/400**

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

**Library Name**

Supply the name of the library in which the query definitions reside. (Wildcards are not permitted.)

**Note:** When you create a synonym for Query/400 on the IBM i platform, standard IBM i naming conventions apply to the target data source. Therefore, the Adapter for Query/400 supports the use of double-quotation marks around any library name and/or file name that contains lower case or NLS characters.

Click *Submit* to continue.

**Application**

Select an application directory. The default value is baseapp.
Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Do not save library information

Select this check box if you do not wish to save the library of the stored query in the metadata.

This selection ensures that the specific execution is based on the current library path of the connected user at run time.

Note that the library referred to here is not the library specification of the files used within the query, but rather where the query itself is located.

Select objects for synonym creation

To select all names in the list, select the check box to the left of the Default Synonym Name column heading. (If the library contains a large number of query definitions, this check box will not appear, however, synonyms will be created for all definitions automatically.)

To select specific names, click the corresponding check boxes.

Not all listed objects are data-related. Be sure to select those that are appropriate for creating synonyms.

Note: Mixed case names or names with NLS character will appear in double quotation marks. However, the double quotation marks will be replaced by underscore characters in the Default Synonym Name column (see below).

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Note: If you see a synonym name surrounded by underscore characters (as described in the previous note), you can remove the underscores if you wish.
**Example: Creating a Synonym for Query/400**

To generate the following synonym from the Create Synonym panes:

1. Specify a library in the Library Name field, then click **Submit**.

2. On the second Create Synonym pane, choose a query from the Synonym list and click **Create Synonym**.

   The synonym is created and added under the specified application directory (the default is baseapp).

   A status window displays the message: *Created Successfully*.

3. From the message window, click **Applications** on the menu bar.

4. Open the **baseapp** application folder in the navigation pane and click the synonym.

5. Choose **Edit as Text** from the menu to view the generated Master File, then choose **Edit Access File as Text** to view the corresponding Access File.

**Sample Generated Master File:**

```plaintext
FILENAME=CUSTSUM, SUFFIX=QRY, $  
SEGMENT=TMPFILE, SEGTYPE=S0, $  
  FIELDNAME=YEAR, ALIAS=YEAR, USAGE=I9, ACTUAL=I4,  
  TITLE='YEAR', $  
  FIELDNAME=MONTH, ALIAS=MONTH, USAGE=I9, ACTUAL=I4,  
  TITLE='MONTH', $  
  FIELDNAME=DAY, ALIAS=DAY, USAGE=I9, ACTUAL=I4,  
  TITLE='DAY', $  
  FIELDNAME=CUSTOMER, ALIAS=CUSTOMER, USAGE=A25, ACTUAL=A25,  
  TITLE='CUSTOMER', $  
  FIELDNAME=QUANTITY, ALIAS=QUANTITY, USAGE=P15.2C, ACTUAL=P8,  
  TITLE='QUANTITY', $  
  FIELDNAME=REVENUE, ALIAS=REVENUE_WO_TAX, USAGE=P15.2C, ACTUAL=P8,  
  TITLE='REVENUE_WO_TAX', $  
  FIELDNAME=CUSTSUM, ALIAS=FILE1, USAGE=A32, ACTUAL=A32,  
  ACCESS_PROPERTY=(NEED_VALUE), XDEFAULT='ACCT/CUSTOMER', $  
```

**Sample Generated Access File:**

```plaintext
SEGNAME=TMPFILE, QIQR=ACCT/CUSTSUM, $  
```
### Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td><strong>Option</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>
The Adapter for Rdb allows applications to access Rdb data sources. The adapter converts application requests into native Rdb statements and returns optimized answer sets to the requesting application.

**Topics:**

- Preparing the Rdb Environment
- Configuring the Adapter for Rdb
- Managing Rdb Metadata
- Using Multiple Rdb DBMS Files
- Using Multischema Rdb DBMS Files
- Rdb Database Driver Performance
Preparing the Rdb Environment

Oracle Rdb allows two types of installation:

- **Standard.** Supports only one Rdb release level on a machine. No preparation is required to use the adapter in a Standard Rdb environment.

- **Multi Version.** Supports multiple Rdb release levels on the same machine. To switch between releases, Multi Version supplies a script, which sets up logically to point to standard names, such as SQL$, at specific release files, such as SQL$61.EXE, SQL$70.EXE, SQL$71.EXE, and SQL$72.EXE.

To use the adapter in a Multi Version environment, prior to server startup, your Rdb environment must be set up to access the database file release level that corresponds to the release level selected during configuration of the adapter. To enable switching between Rdb releases, your site might use the Rdb script DECRDB$SETVER, a site-specific script, or a symbol. For details on how Rdb release level switching is implemented at your site, see your OpenVMS Administrator.

Configuring the Adapter for Rdb

**In this section:**
- Overriding the Default Connection
- Controlling the Connection Scope

**How to:**
- Declare Connection Attributes
- Declare Connection Attributes Manually

**Example:**
- Declaring a Connection to ORDERS.RDB

**Reference:**
- Connection Attributes for Rdb

Configuring the adapter consists of specifying connection and authentication information for the connection you want to establish.

To connect to an Rdb database server, the adapter requires connection and authentication information. You supply this information using the SET SERVER command. You can:
Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**.
   or
   From the Data Management Console, expand the **Adapters** folder.
   The Adapters folder opens.

2. Expand the **Available** folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select **Configure**.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click **Configure**. The configured adapter is added to the Adapters list in the navigation pane.

**Reference: Connection Attributes for Rdb**

The Rdb adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the **Configure** button.

**Server**

Full path to an Rdb data source, or a logical name, such as SQL$DATABASE, which contains the full path. Rdb limits this value to 31 characters. If the full path exceeds this limit, you must specify a logical name to point to the full path.

- **Full Path**. Full path specification must be in the following form: device_name:[directory]file.RDB. The RDB extension is required.
Logical Name. To use this method, the logical must be set prior to server startup. The trailing blank is optional.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Note: Only one SET SERVER command may be active at any given moment; the last command issued is the active Rdb DBMS file.

Rdb multischema DBMS files are not supported for metadata creation purposes, but are valid for data access purposes provided that the Access File TABLENAME= value points to the table properly. For more information about configuration and metadata creation, see Using Multischema Rdb DBMS Files on page 1911.

Syntax: How to Declare Connection Attributes Manually

The adapter connects to Rdb using the credentials of the operating system user impersonated by the data access agent.

ENGINE SQLRDB SET SERVER server

where:

SQLRDB

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

server

Is the full path to an Rdb data source, or a logical name, such as SQL$DATABASE, which contains the full path. Rdb limits this value to 31 characters. If the full path exceeds this limit, you must specify a logical name to point to the full path.

Full Path. Full path specification must be in the following form: device_name:[directory]file.RDB. The RDB extension is required.

Logical Name. To use this method, the logical must be set prior to server startup. The trailing blank is optional.
**Note:** Once the initial SET SERVER command is saved in a profile, you can manually declare additional connections to more than one Rdb database by including any number of additional Rdb ATTACH ALIAS commands and editing the Access File to properly point to the TABLENAME= value at the alias. For more information about configuration and metadata creation in this context, see *Using Multischema Rdb DBMS Files* on page 1911.

**Example: Declaring a Connection to ORDERS.RDB**

The following example shows how to declare a connection to the ORDERS.RDB data source, located in the OUTBOUND directory on disk.

```
ENGINE SQLRDB SET SERVER DISK$SHIPPING:[OUTBOUND]ORDERS.RDB
```

**Overriding the Default Connection**

**How to:**

Change the Default Connection

**Example:**

Selecting the Default Connection

Once connections have been defined, the connection named in the last SET SERVER command serves as the default connection. You can override this default by reissuing the SET SERVER command.

**Syntax:**

**How to Change the Default Connection**

```
ENGINE SQLRDB SET DEFAULT_CONNECTION connection
```

**where:**

```
SQLRDB
```

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

```
connection
```

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```
Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  FOC1671, Command out of sequence.

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

  ENGINE SQLRDB SET DEFAULT_CONNECTION SAMPLENAME

Controlling the Connection Scope

**How to:**

Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:**

**How to Control the Connection Scope**

  ENGINE SQLRDB SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}

where:

  SQLRDB
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

  FIN
  
  Disconnects automatically only after the session has been terminated. FIN is the default value.

  COMMAND
  
  Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.
COMMIT

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Rdb Metadata

In this section:
Creating Synonyms
Rdb Data Type Support

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Rdb data types.

Creating Synonyms

How to:
Create a Synonym

Example:
Sample Generated Synonym

Reference:
Synonym Creation Parameters for Rdb
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each Rdb table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.
**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   
   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   
   The *Select adapter to configure or Select connection to create synonym* pane opens.

3. Click a connection for the configured adapter.
   
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.
   
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

**Reference: Synonym Creation Parameters for Rdb**

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.
Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Location of External SQL Scripts**

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.
During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.
**Customize data type mappings**

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Rdb Data Type Support* on page 1904.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Owner/Schema**

The user account that created the object or a collection of objects owned by a user.

**Type**

The object type (Table, View, and so on).

**Select tables**

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the *Select All* button.
- To select specific tables, select the corresponding check boxes.

**Example: Sample Generated Synonym**

An Adapter for Rdb synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

**Generated Master File nf29004.mas**

```plaintext
FILE=DIVISION, SUFFIX=SQLRDB ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON ,$
```

**Generated Access File nf29004.acx**

```plaintext
SEGNAME=SEG1_4, 'TABLENAME=RDB$HANDLE.NF29004',
CONNECTION=DSN_A, KEYS=1, WRITE=YES ,$
```
**Reference:**  **Access File Keywords**

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the Rdb table.</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is:</td>
</tr>
<tr>
<td></td>
<td>CONNECION(=)connection)</td>
</tr>
<tr>
<td></td>
<td>CONNECION(=') indicates access to the local database server.</td>
</tr>
<tr>
<td></td>
<td>Absence of the CONNECTION attribute indicates access to the default</td>
</tr>
<tr>
<td></td>
<td>database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table.</td>
</tr>
<tr>
<td></td>
<td>Range is 0 to 64. Corresponds to the first (n) fields in the Master File</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>Indicate a name of the index in a database, uniqueness, name, and</td>
</tr>
<tr>
<td>INDEX_UNIQUE</td>
<td>order of the indexed column(s).</td>
</tr>
<tr>
<td>INDEX_COLUMNS</td>
<td></td>
</tr>
<tr>
<td>INDEX_ORDER</td>
<td></td>
</tr>
</tbody>
</table>

**Reference:**  **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If</td>
</tr>
<tr>
<td></td>
<td>an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td>Note:</td>
<td>To update the synonym, it is strongly recommended that you use the</td>
</tr>
<tr>
<td></td>
<td>graphical interface provided by the <strong>Open</strong> option, rather than manually</td>
</tr>
<tr>
<td></td>
<td>editing the Master File.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

Rdb Data Type Support

The following tables describe how the server maps Rdb data types.

<table>
<thead>
<tr>
<th>Oracle Rdb Data Type</th>
<th>Server Data Type</th>

<td>32-bit FLOAT(n), where (n) is less than 25.</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>D20.2</td>
<td>D8</td>
<td>64-bit FLOAT(n), where (n) is 25 or greater.</td>
</tr>
</tbody>
</table>
### Oracle Rdb Data Type

<table>
<thead>
<tr>
<th>Oracle Rdb Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMERIC, DECIMAL (p,s)</td>
<td>D20.2 D8</td>
<td>Same as REAL or DOUBLE PRECISION. 8 bytes; value range -2 * 10(^{307}) to 2 * 10(^{308}).</td>
</tr>
<tr>
<td>BIGINT (-2(^{63}) ... 2(^{63}) - 1)</td>
<td>D20.2 D8</td>
<td></td>
</tr>
</tbody>
</table>

The following table lists how the server maps Character data types. This mapping can be changed based on the value of LONGCHAR. The default value is ALPHA.

<table>
<thead>
<tr>
<th>Oracle Rdb Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>n is an integer between 1 and 256.</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td></td>
<td>n is an integer greater than 256.</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>n is an integer between 1 and 256.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td></td>
<td>n is an integer greater than 256.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>LONGVARCHAR (n)</td>
<td>n is an integer between 1 and 256.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td></td>
<td>n is an integer greater than 256.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
</tbody>
</table>

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.
Using Multiple Rdb DBMS Files

Example:
Completing Setup and Metadata Creation Steps for Multiple Rdb DBMS Files

Reference:
Considerations For Sites That Have Upgraded From a Release Prior to 768

In native Rdb, within the same session you can access two or more tables that exist in different physical Rdb DBMS files by issuing one or more ATTACH ALIAS commands using the following syntax,

```
ATTACH 'ALIAS alias FILENAME filename'
```

and referencing a specific ALIAS or RDB$HANDLE for the current default file in each SQL request you issue.

Although you can accomplish the same task using the Adapter for the Rdb DBMS, the adapter metadata-creation facility is limited to the single default connection handle. Therefore, if you wish to use multiple Rdb tables, you must add one or more SQL Passthru ATTACH commands to the server profile (or a group or user profile), and complete a few extra metadata-creation steps, as described in Completing Setup and Metadata Creation Steps for Multiple Rdb DBMS Files on page 1907.

If you follow these instructions, you will be able to JOIN across Rdb DBMS files and access Rdb data remotely on a subserver from a client connection (using a SUFFIX=EDA synonym).

The details of the extra steps for metadata creation will vary by site, however, two general approaches are available:

- If a single Rdb DBMS file with a common set of tables is available as a dictionary, you can configure this Rdb file as the default connection. The steps that follow are as simple as the standard synonym creation process, with the addition of a manual edit to the resulting Access File to point the TABLENAME= value at the desired ATTACH alias. Completing Setup and Metadata Creation Steps for Multiple Rdb DBMS Files on page 1907 illustrates this process.

- If an Rdb DBMS file is not available as a single dictionary, after configuring an initial connection, creating metadata, and editing the Access File TABLENAME= attribute, you can reconfigure and repeat the synonym creation and Access File editing steps as many times as necessary for the additional Rdb targets.

Important: The Adapter for Rdb has been stabilized. Therefore, Information Builders has no plans to support multiple connections directly through the adapter, except by using the configuration techniques described in this topic.
Completing Setup and Metadata Creation Steps for Multiple Rdb DBMS Files

Example: Completing Setup and Metadata Creation Steps for Multiple Rdb DBMS Files

This example illustrates the setup and metadata creation steps for multiple Rdb DBMS files. The example assumes that an Rdb DBMS file with all tables is available as a template dictionary and for use in metadata creation. You can adapt this example to suit your needs.

1. Determine what Rdb files are needed. For this example, the file names are:

   CORPTABLES.RDB,
   CORPDATA2006.RDB
   CORPDATA2007.RDB
   CORPDATA2008.RDB

   These files reside in the directory DISK$DUA0:[RDB].

   CORPTABLES is an empty DBMS template that is cloned for each year’s data and provides a dictionary for use in the synonym creation process. In addition, logicals that match the physical file names are used to avoid the Rdb 31-character physical limit and to facilitate coding in case the location changes in the future.

2. To ensure that the logicals are always available (and known to the server at start up time), edit the following file

   EDACONF [.BIN]EDAENV.COM

   and add a logical name reference (of 31 characters or less) for each Rdb DBMS file to be accessed. For example:

   $ DEFINE CORPTABLES DISK$DUA0:[RDB]CORPTABLES.RDB
   $ DEFINE CORPDATA2006 DISK$DUA0:[RDB]CORPDATA2006.RDB
   $ DEFINE CORPDATA2007 DISK$DUA0:[RDB]CORPDATA2007.RDB
   $ DEFINE CORPDATA2008 DISK$DUA0:[RDB]CORPDATA2008.RDB

   Save your changes.

   Note:

   - If a generic application setup batch file with the desired logical is available and does not force a process exit, you can call that batch file from EDAENV.COM and avoid the individual entries described above.

   - If the desired logicals are already available, you can skip this step altogether because the logicals are automatically issued when you boot your machine.

3. Assuming you have edited the EDAENV file as described in step 2, start or restart your server.
4. During Rdb adapter configuration, choose the standard options for enabling Rdb data access and supply the following logical name for the server:

**CORPTABLES:**

The resulting profile entry would looks as follows:

```
ENGINE SQLRDB SET SERVER CORPTABLES:
```

5. Using the Web Console's edit facility or another editor, modify the global profile, edasprof.prf (or possibly a group or user profile if you are configuring for group or personal profile-based behavior) to add an ATTACH ALIAS command for each of the additional Rdb files. This step will make the Rdb database files visible as aliases to the default database. For this example, the following code was added after the SET SERVER line in the profile:

```
ENGINE SQLRDB SET SERVER CORPTABLES:
SQL RDB ATTACH 'ALIAS CORPDATA2006 FILENAME CORPDATA2006:' ;
END
SQL RDB ATTACH 'ALIAS CORPDATA2007 FILENAME CORPDATA2007:' ;
END
SQL RDB ATTACH 'ALIAS CORPDATA2008 FILENAME CORPDATA2008:' ;
END
```

**Note:**

- The semi-colon and END statements are required.
- The ATTACH statements must follow the initial SET SERVER command. (Placement before the SET SERVER command will cause a crash.)
- You can issue additional SET SERVER statements after the ATTACH statements.

6. At this point, if you have metadata from a prior installation it is good practice to determine if you can use your existing metadata as is, if you need to modify it, or if you need to create new (additional) metadata that is distinct from what already exists. Depending on your needs, you may be done or you may need to continue with either Step 7 or Step 8.

- For new installations (that is, those with no prior metadata), continue with Step 7.

- In releases prior to 7.6.8, a synonym was either prefixed or not prefixed depending on how the metadata was created or, possibly, edited at a later time for a specific value. If the metadata for a given table is available and the TABLENAME=value attribute in the Access File points at the appropriate SQL aliastablename (or is not prefixed for data that uses the default connection), then there is no need to modify the given synonym in order to access the data. If all synonyms are of this type and no additional new metadata is desired, you are done.
If additional new synonyms are desired, or if prefixes on existing synonyms need to change, continue with Step 7 to create the new metadata and then go to Step 8 to edit the Access File TABLENAME=value for the existing and new synonyms.

7. Whether you are creating a synonym for the first time or re-creating a synonym that existed in a prior release, you can use the Web Console or the DMC synonym creation facility. When prompted, select the desired Rdb tables using the connection:

   CORPTABLES:

8. After any needed metadata has been created, edit the Access Files that needs to change (using the Web Console editor or another editor) to have a TABLENAME= value that is prefixed with the appropriate ALIAS reference.

   To complete this step from the Web Console, locate the synonym whose Access File you need to edit, click it, and select Edit Access File as Text from the menu.

   For instance, in the Access File TABLENAME entry for the 2007 Sales table initially looks like this:

   TABLENAME='RDB$HANDLE.SALES',

   The single quotation marks are required since the $ in RDB$HANDLE is regarded as a special character.

   The edited version would look as follows:

   TABLENAME='CORPDATA2007.SALES',

   In this instance, the single quotation marks are optional since CORPDATA2007 does not contains a special character.

9. Repeat step 8, as many time as necessary to account for all metadata whose access requires an ATTACH ALIAS command.

   Tip: As an alternative to editing each file individually, you can create a batch script that edits the RDB$HANDLE string for groups of files at one time.
Note:

- If you prefer to use a different default Rdb file rather than the current one, you can switch the configuration value to the preferred value once metadata creation is done. To do so, return to the Rdb adapter configuration pane and change the Rdb target. Subsequently, any Access File using an explicit ATTACH ALIAS prefix, the RDB$HANDLE prefix, or no prefix at all will use the associated file as the source of data.

- If a single Rdb DBMS file is not available as a template for all tables, you can follow the basic configuration and synonym creation process, however, you will need to reconfigure the Rdb target, then repeat Step 7 (metadata creation) for each individual Rdb target, and continue to Step 8 (Access File editing).

Tip: An orderly approach is to create all of the synonyms, repeat the reconfiguration step as needed, then edit the Access Files.

Reference: Considerations For Sites That Have Upgraded From a Release Prior to 768

Releases prior to 768 recommended similar metadata creation and Access File editing steps (with TABLENAME= prefix.table and a SERVER= prefix value) for JOINs, and, in addition, required that the profile be edited to eliminate the SET SERVER command and to include the SQL APT=OFF command at runtime.

While not explicitly documented, this method enabled remote access (using SUFFIX=EDA) to Rdb data because APT=OFF allowed Rdb to pick up data using the SERVER= value from the Access File.

While it is not necessary for sites that currently use this configuration method to change or reconfigure in Version 7 Release 6.8, there are distinct advantages in doing so:

- When the SET SERVER command was removed, as required under the prior configuration method, the Web Console synonym creation capability was disabled. Since it is no longer necessary to remove the SET SERVER command, keeping the command will enable you to create synonyms for Rdb from the Web Console without any secondary configurations.

- The need to remove the SET SERVER command and turn APT to OFF may have provided sufficient justification for configuring a secondary server to be used exclusively for JOIN and remote (SUFFIX=EDA) purposes under the prior method. Under the new method, these reasons have been eliminated. Therefore, you may wish to consider eliminating the secondary server in order to save maintenance overhead and computer cycles. Using the explicit ATTACH ALIAS steps described in this document also provides clearer information about how data is being accessed.

Note that it is not necessary to remove the SERVER= value from the Access Files since this information is not used in this context and is, therefore, ignored.
Using Multischema Rdb DBMS Files

A multischema Rdb DBMS file is, in effect, a file with multiple schemas within one physical file and, as such, two part names in a non-multischema file become three part names (that is, the two part name schema.table, where ATTACH ALIAS assigns the schema name, becomes catalog.schema.table). As a result, you can ATTACH a single file (rather than a default plus various aliases).

The Adapter for Rdb does not support multischema Rdb DBMS files for metadata creation. However, if a non-multischema Rdb file is available as a template for tables, synonym creation and data access may be done in much the same way as described previously for multiple Rdb DBMS files (see Completing Setup and Metadata Creation Steps for Multiple Rdb DBMS Files on page 1907), with the following variations.

**For a multischema Rdb DBMS file**, you can use either of the following commands for data access at run time

ENGINE SQLRDB SET SERVER multischema_target;

or, as a non-aliased ATTACH command,

SQL RDB ATTACH 'FILENAME multischema_target';
END

With either of these commands the proper TABLENAME= value is rendered in the Access File as a three part name—for example,

TABLENAME=ADMINISTRATION.PERSONNEL.EMPLOYEES,

which is a name from Rdb's standard multischema example used in non alias mode.

**For an explicitly aliased multischema ATTACH command, use the following method.**

A multischema Rdb DBMS file used with an ATTACH ALIAS command requires (as Rdb’s SQL$ requires) that you add a SET QUOTING RULES command to ensure that the execution process for the table is properly referenced. The easiest way to do this is to add the command in the same place as the ATTACH ALIAS command. (Note that you can place the QUOTING RULES command before or after the ATTACH command, but it must be executed before actual data access.)

For example (also using Rdb’s multischema example, but in alias mode), add the following code:

SET QUOTING RULES 'SQL92';
END
SQL RDB ATTACH 'ALIAS CORP FILENAME CORPORATE_DATA:' ;
END

A proper TABLENAME= value is a specially quoted three part name such as:

TABLENAME='"CORP.ADMINISTRATION".PERSONNEL.EMPLOYEES',

Adapted Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS
Note the use of enclosing single quotation marks: these are required because the double quotation marks are considered special characters to be passed to Rdb, which in turn processes the "CORP.ADMINISTRATION" portion properly as the alias due to Rdb's SET QUOTING RULES command, which is used in the profile.

Rdb Database Driver Performance

The default of Rdb is to open tables in read/write mode unless told otherwise. The Server supports read/write operations, so this is appropriate behavior. However, Rdb read/write operations consume more resources and are slower, even if just a select is being done. Applications can set Rdb opens to Read-only on a per request basis or a per session basis to enhance resource usage and speed performance. In either case, a commit should be done to ensure that prior work is complete.

On a session basis, add the following to the EDASPROF.PRF after the SQL SQLRDB SET SERVER command:

```
SQL SQLRDB COMMIT ;
SQL SQLRDB SET DECLARE TRANSACTION READ ONLY ;
```

On a per request basis (for example, immediately before a TABLE request) the usage is:

```
SQL SQLRDB COMMIT ;
SQL SQLRDB SET TRANSACTION READ ONLY ;
```
Using the Adapter for Red Brick

The Adapter for Red Brick allows applications to access Red Brick data sources. The adapter converts application requests into native Red Brick statements and returns optimized answer sets to the requesting application.

Topics:
- Preparing the Red Brick Environment
- Configuring the Adapter for Red Brick
- Managing Red Brick Metadata
- Customizing the Red Brick Environment
- Optimization Settings
Preparing the Red Brick Environment

**How to:**

Set Up the Environment on Windows
Set Up the Environment on UNIX

The Adapter for Red Brick minimally requires the installation of the IBM Red Brick Client 32 ODBC software. After installation, ODBC must be configured to allow you to connect to a local or remote Red Brick database server.

**Procedure: How to Set Up the Environment on Windows**

On Windows, the Red Brick environment is set up during the installation of Red Brick.

**Procedure: How to Set Up the Environment on UNIX**

1. Specify the location of the Red Brick database you wish to access using the UNIX environment variable $RB_CONFIG. For example, to set the home directory for the Red Brick software to /rdbms/red61, specify:

   ```
   RB_CONFIG=/rdbms/red
   export RB_CONFIG
   ```

2. Define the $HOME/.odbc.ini file, which describes the Red Brick data sources. You can use the ODBCINI variable instead of $HOME/.odbc.ini.

Configuring the Adapter for Red Brick

**In this section:**

Declaring Connection Attributes
Overriding the Default Connection
Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Declaring Connection Attributes

**How to:**
Declaring Connection Attributes
Declaring Connection Attributes Manually

**Example:**
Declaring Connection Attributes

**Reference:**
Connection Attributes for Red Brick
Updating the Connection String

In order to connect to a Red Brick database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one Red Brick database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to Red Brick Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

**Procedure:** How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**.
From the Data Management Console, expand the \textit{Adapters} folder.

The Adapters folder opens.

2. Expand the \textit{Available} folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select \textit{Configure}.

The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click \textit{Configure}. The configured adapter is added to the Adapters list in the navigation pane.

\textbf{Reference:} \textbf{Connection Attributes for Red Brick}

The Red Brick adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the \textit{Configure} button.

\textbf{Connection name}

Logical name used to identify this particular set of connection attributes. The default is CON01.

\textbf{Datasource}

The data source name (DSN). There is no default data source name. You must enter a value.

\textbf{User}

Authorization ID to connect to the source.

\textbf{Password}

Password associated with the authorization ID.

\textbf{Select profile}

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.
If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:**

**How to Declare Connection Attributes Manually**

ENGINE SQLRED SET CONNECTION_ATTRIBUTES connection
DSN_name/userid,password

where:

**SQLRED**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**

Is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between *connection* and *DSN_name*.

**DSN_name**

Is the Red Brick Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

**userid**

Is the primary authorization ID by which you are known to Red Brick.

**password**

Is the password associated with the primary authorization ID.

**Example:**

**Declaring Connection Attributes**

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the Red Brick DSN named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE SQLRED SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS
```
Reference: Updating the Connection String

The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Web Console Migrate option migrates your server settings to the newer release. To access this option, select Workspace, then Configuration/Monitor from the menu bar. Right-click Migrate from the Server folder in the navigation pane, and select Configure. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the Migrate button. This is the recommended approach.

If you choose not to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=value.

For example, suppose that prior 7.6.1 the connection was defined as:

```plaintext
ENGINE SQLRED SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
```

When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

```plaintext
CONNECTION=DSN_A
```

If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

```plaintext
ENGINE SQLRED SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
```
Overriding the Default Connection

**How to:**

Change the Default Connection

**Example:**

Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:**

**How to Change the Default Connection**

```
ENGINE SQLRED SET DEFAULT_CONNECTION connection
```

where:

- **SQLRED**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  - Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:
    ```
    FOC1671, Command out of sequence
    ```

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:
  ```
  FOC1671, Command out of sequence.
  ```

**Example:**

**Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```
ENGINE SQLRED SET DEFAULT_CONNECTION SAMPLENAME
```
Controlling the Connection Scope

How to:
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLRED SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

**SQLRED**
- Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**FIN**
- Disconnects automatically only after the session has been terminated. FIN is the default value.

**COMMAND**
- Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

**COMMIT**
- Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing Red Brick Metadata

In this section:
Creating Synonyms
Red Brick Data Type Support
Controlling the Mapping of Variable-Length Data Types
Trailing Blanks in SQL Expressions
Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Red Brick data types.

Creating Synonyms

How to:
Create a Synonym

Example:
Sample Generated Synonym

Reference:
Synonym Creation Parameters for Red Brick
Mapping Red Brick Comments Into a Synonym
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each Red Brick table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.
**Procedure:** How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click **Applications**.
   
   The Applications page opens.

2. Click the **New** button and select **Synonym** from the drop-down menu.
   
   The **Select adapter to configure or Select connection to create synonym** pane opens.

3. Click a connection for the configured adapter.
   
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click **Create Synonym**.
   
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**
- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting **Create Synonym**.
- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see **Validation for Special Characters and Reserved Words** on page 2821.

**Reference:** Synonym Creation Parameters for Red Brick

The Red Brick adapter is under the **SQL** group folder.

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing **External SQL Scripts** from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters ("," or "/") and comments.
Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Location of External SQL Scripts**

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the **Base Location** field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the **Document Name** field, enter the file name with or without wild card characters.

- In the **Document Extension** field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the **Base Location** field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The **Document Extension** is understood to be MBR. You can enter this value explicitly or leave the input box blank.
During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first. If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

**With foreign key**

Select the *With foreign key* check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.
Prefix/Suffix
If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings
To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Red Brick Data Type Support on page 1929.

Overwrite Existing Synonyms
To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name
This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema
The user account that created the object or a collection of objects owned by a user.

Type
The object type (Table, View, and so on).

Select tables
Select tables for which you wish to create synonyms:

☑ To select all tables in the list, click the Select All button.
☑ To select specific tables, select the corresponding check boxes.

Example:  Sample Generated Synonym
An Adapter for Red Brick synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.
Generated Master File nf29004.mas

FILE=DIVISION, SUFFIX=SQLRED ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON ,$

Generated Access File nf29004.acx

SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=DSN_A,KEYS=1,WRITE=YES,$

Reference: Mapping Red Brick Comments Into a Synonym

When you generate a synonym for a Red Brick table, the adapter maps each:

- Red Brick table comment from the Red Brick catalog to a Remark attribute in the Master File of the synonym.
- Red Brick column comment from the Red Brick catalog to a Description attribute in the Master File of the synonym.

Reference: Access File Keywords

This chart describes keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the Red Brick table. The value assigned to this attribute can include the name of the owner (also known as schema) as follows: TABLENAME=[owner.]table</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is: CONNECTION=connection</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first n fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
</tbody>
</table>
Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.

- KEYFLD is the FIELDNAME of the common column from the parent table.
- IXFLD is the FIELDNAME of the common column from the related table.

KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.

**Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEYFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td>IXFLD</td>
<td>Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).</td>
</tr>
</tbody>
</table>

| AUTO_INCREMENT | Set to Yes to enable autoincrementing. |
| START | Initial value in incrementing sequence |
| INCREMENT | Increment interval. |

Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
| Data Management              | Followed by these options, if applicable: **Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.) **Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted. **Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values. **Reorganize.** Recreates the data source table preserving original data. **Note:** This option is not available in the Web Console.
### Impact Analysis
Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS* manual for details about Impact Analysis reports.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

### Red Brick Data Type Support
The following tables describe how the server maps Red Brick data types.

<table>
<thead>
<tr>
<th>Red Brick Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>USAGE</td>
<td>ACTUAL</td>
</tr>
<tr>
<td><strong>Date-Time Data Types</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DATE</td>
<td>HYYMD</td>
<td>DATE</td>
</tr>
<tr>
<td>TIME</td>
<td>HHISs</td>
<td>HHISs</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>HYYMDm</td>
<td>HYYMDm</td>
</tr>
<tr>
<td><strong>Numeric Data Types</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>TINYINT</td>
<td>I6</td>
<td>I4</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>I6</td>
<td>I4</td>
</tr>
<tr>
<td>REAL</td>
<td>D20.2</td>
<td>D8</td>
</tr>
</tbody>
</table>
### Remarks

#### Server Data Type

<table>
<thead>
<tr>
<th>Red Brick Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTUAL</td>
<td>USAGE</td>
<td>ACTUAL</td>
</tr>
<tr>
<td>DOUBLE PRECISION, FLOAT</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td>NUMERIC, DECIMAL</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td>INTEGER</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Remarks

- **SAME AS REAL OR DOUBLE PRECISION.**
- **$2^{31} = 2,147,483,648.$**

### Other Data Types

- **SERIAL**

  - **USAGE:** P20.2
  - **ACTUAL:** P8P10

  - **Remarks:** The SERIAL data type is a special case of the INTEGER data type. There can be only one SERIAL column in any table. SERIAL data types are not allowed in precomputed view definitions, including view columns, view table columns, and predicates. When defined, it MUST BE specified as NOT NULL. If FIELDTYPE=R is set in the Master File, sample data can not be inserted. Supported as the Surrogate Key.

The following table lists how the server maps Character data types. This mapping can be changed based on the value of LONGCHAR. The default value is ALPHA.

<table>
<thead>
<tr>
<th>Red Brick Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR ($n$)</td>
<td>$n$ is an integer between 1 and 256.</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td></td>
<td></td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td></td>
<td>$n$ is an integer between 257 and 2000.</td>
<td>TX50</td>
<td>TX</td>
</tr>
</tbody>
</table>
### Controlling the Mapping of Variable-Length Data Types

**Remarks**
- VARCHAR \( n \) is an integer between 1 and 256.
- VARCHAR \( n \) is an integer between 257 and 4000.

<table>
<thead>
<tr>
<th>Red Brick Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR ( n )</td>
<td>( n ) is an integer between 1</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td></td>
<td>and 256.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td></td>
<td>( n ) is an integer between 257</td>
<td>AnV</td>
<td>TX50</td>
</tr>
<tr>
<td></td>
<td>and 4000.</td>
<td>AnV</td>
<td>TX</td>
</tr>
</tbody>
</table>

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.

### Syntax: How to Control the Mapping of Variable-Length Data Types

```sql
ENGINE SQLRED SET VARCHAR {ON | OFF}
```

**Where:**
- `SQLRED`
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
- `ON`
  - Maps the Red Brick data type VARCHAR as variable-length alphanumeric (AnV). ON is the default value.
- `OFF`
  - Maps the Red Brick data type VARCHAR as alphanumeric (A).
Trailing Blanks in SQL Expressions

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

```
ENGINE SQLRED SET TRIM_LITERALS ON
```

is available to ensure backward compatibility.

Changing the Precision and Scale of Numeric Columns

**How to:**

Override the Default Precision and Scale

**Example:**

Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

```
ENGINE SQLRED SET CONVERSION RESET
ENGINE SQLRED SET CONVERSION format RESET
ENGINE SQLRED SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLRED SET CONVERSION format [PRECISION MAX]
```

where:

**SQLRED**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.
**format**

Is any valid format supported by the data source. Possible values are:

- **INTEGER** which indicates that the command applies only to INTEGER columns.
- **DECIMAL** which indicates that the command applies only to DECIMAL columns.
- **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.

- **FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.
If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.

**Example: Setting the Precision and Scale Attributes**

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

`ENGINE SQLRED SET CONVERSION INTEGER PRECISION 7`

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

`ENGINE SQLRED SET CONVERSION FLOAT PRECISION 14 3`

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

`ENGINE SQLRED SET CONVERSION INTEGER RESET`

The following example shows how to set the precision and scale attributes for all fields to the defaults:

`ENGINE SQLRED SET CONVERSION RESET`

### Customizing the Red Brick Environment

**In this section:**

- Specifying a Timeout Limit
- Obtaining the Number of Rows Updated or Deleted

The Adapter for Red Brick provides several parameters for customizing the environment and optimizing performance.

### Specifying a Timeout Limit

**How to:**

Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to Red Brick.
**Syntax: How to Issue the TIMEOUT Command**

`ENGINE SQLRED SET TIMEOUT {nn|0}`

where:

**SQLRED**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**nn**
Is the number of seconds before a time-out occurs. 30 is the default value.

**0**
Represents an infinite period to wait for a response.

**Obtaining the Number of Rows Updated or Deleted**

**How to:**
Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:** How to Obtain the Number of Rows Updated or Deleted

`ENGINE SQLRED SET PASSRECS {ON|OFF}`

where:

**SQLRED**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**
Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.
**Optimization Settings**

**OFF**

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

**Optimization Settings**

**In this section:**
- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields
- Optimizing Requests to Pass Virtual Fields Defined as Constants
- Optimizing Outer Joins

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

**Optimizing Requests**

**How to:**

Optimize Requests

**Example:**

SQL Requests Passed to the RDBMS With Optimization ON

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

How to Optimize Requests

```
SQL SQLRED SET {OPTIMIZATION|SQLJOIN} setting
```

where:

**SQLRED**

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.
SQLJOIN

Is a synonym for OPTIMIZATION.

setting

Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.

Both OPTIMIZATION settings produce the same report.

Note: The OFF setting is not recommended since Red Brick supports only one active SQL per connection and will return:

** ERROR ** (10167) Attempt to initiate a new SQL...with results pending

Example: SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

SQL SQLRED SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
IF DEPARTMENT EQ 'MIS'
END

In a trace operation, you will see the following output:

AGGREGATION DONE ...
SELECT T2.EID,T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID,T1.LN
ORDER BY T2.EID,T1.LN;
Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

How to:
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

Example:
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

Reference:
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

SQL  SQLRED  SET  OPTIFTHENELSE  {ON|OFF}
where:

SQLRED
Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

ON
Enables IF-THEN-ELSE optimization. This is the default.

OFF
Disables IF-THEN-ELSE optimization.
There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```
SQL SQLRED SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```
SELECT T1.'LN',T1.'FN',T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' ')) AND (T1.'DPT' = 'MIS'))));
```

**Example:** Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```
SQL SQLRED SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2 ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END
```
The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = 'SMITH')));
```

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
WHERE (((NOT (T1.'LN' = 'SMITH'))) AND (T1.'LN' = 'JONES'));
```

**Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False**

```sql
SQL SQLRED SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END
```

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```

**Reference: SQL Limitations on Optimization of DEFINE Expressions**

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  ```sql
  X=X+1;
  ```
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.
  
  **Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.

- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.

- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

  **Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.

- STATIC SQL.

- IF/WHERE DDNAME.

- Partial date selection.

### Optimizing Requests to Pass Virtual Fields Defined as Constants

#### Example:

- Passing Numeric Constants
- Passing a CHAR Constant
- Passing CHAR and INTEGER Constants

A virtual field defined as a constant is passed directly to an SQL database engine (RDBMS) for optimized processing that takes advantage of RDBMS join, sort, and aggregation capabilities, thus reducing the volume of RDBMS-to-server communication and improving response time. (In prior releases, constants were not passed to the database engine, causing optimization to be turned off.)

Constants in the following formats are passed to the RDBMS: NUMERIC, CHAR, VARCHAR, CHAR/INTEGER combination, and DATE. (Note that a few formats are not passed to the RDBMS; these are CHAR and VARCHAR combination, TIME, and DATETIME.)
When valid constants are passed to an RDBMS engine, a report is calculated based on the defined value(s) and only the calculated subset of records is returned. The extent of data manipulation at the adapter level is limited, thereby improving performance.

**Example:**  **Passing Numeric Constants**

```plaintext
DEFINE FILE SMIX87
INTEGERCONST/I4 = 5
REALCONST/D20.2 = -97995.38
NUMERICCONST/P13.4 = -92999.3647

TABLE FILE SMIX87
  SUM INTEGERCONST REALCONST NUMERICCONST MAX.QUOT.FA01INTEGER
  BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", SUM(5), SUM(-97995.38),
  SUM(-92999.3647), MAX(T2."FA01INTEGER") FROM TMIX83A T2 GROUP
  BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```
The following SQL is generated:

```sql
SELECT T2."FA02INTEGER", MAX('2N'), SUM(5) FROM TMIX83A T2
GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

### Optimizing Outer Joins

The Redbrick adapter can optimize FOCUS OUTER JOINs to SQL. However, the OUTER JOIN optimization depends on native Redbrick capabilities. Non-equality conditions in ON clauses are supported for INNER JOINS only. For OUTER JOINs, non-equality conditions will return:

- A native TMU error
  
  RBS1609,..., RBS1612 An outer join <problem criteria>

  or

- A Redbrick server error
  
  10167 Attempt to initiate a new SQL...with results pending

For more information please refer to IBM Redbrick documentation.
Optimization Settings
Using the Adapter for REST

REST is an acronym for REpresentational State Transfer. REST-style architectures consist of clients and servers. Clients initiate requests to servers and servers process requests and return appropriate responses. REST was initially described in the context of HTTP. It utilizes well-known, well-defined methods like GET, POST, PUT, and DELETE.

A RESTful Web Service is a web service implemented using HTTP and the principles of REST.

The Adapter for REST supports RESTful Web Services, where the response is either XML or JSON (JavaScript Object Notation). For more information, see Using the Adapter for JSON on page 1199 and Using the Adapter for XML on page 2719.

Topics:
- Configuring the Adapter for REST
- Managing RESTful Web Services Metadata
Configuring the Adapter for REST

In this section:
Declaring Connection Attributes
Security for RESTful Web Services

Configuring the adapter consists of specifying connection information and if necessary, authentication information for at least one connection.

Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Example:
Declaring Connection Attributes Manually

Reference:
Connection Attributes for the Adapter for REST

In order to access the RESTful Web Service provider hosting the target web service, the adapter requires connection information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one web services provider by including multiple SET CONNECTION_ATTRIBUTES commands.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
or

From the Data Management Console, expand the Adapters folder.
The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure without Authentication. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for the Adapter for REST

The Adapter for REST is under the Procedures group folder.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Service Description

Is the service description. The available options are:

- none. Indicates a WADL (Web Application Description Language) file, which describes the RESTful Web Service, does not exist.
- WADL. Indicates an XML file that describes the RESTful Web Service.

Base Url

Is the part of the URL that is common for calling all the functionality of a particular RESTful Web Service. Addresses can begin with http:// or https://. For example: http://api.geonames.org.

PROXY Server IP Address

Is the IP address of the proxy server, which intercepts requests and forwards them to the actual server.

PROXY Port

Is the port number on which the proxy server listens. The default port number is 80.
Service Principal Name

Is the name by which a client uniquely identifies an instance of a service. For example: mydaemon/foo:4761.

Certificate

Is the location of locally-stored, user-provided server x.509 certificates for SSL authentication. The certificate file is used to authenticate the server to which the adapter is connecting.

Certificate type

Is the certificate type. The options are:

- trusted. The trusted certificate file (trustedcertfile) points to a file of CA certificates in PEM format, as illustrated below:

```
-----BEGIN CERTIFICATE-----
... (CA certificate in base64 encoding) ...
-----END CERTIFICATE-----
```

A trusted certificate file can contain several CA certificates. You can add text before, between, and after certificates. For example, to provide descriptions of the certificates.

- non-trusted. This option adds Key file, Pass phrase, and Label to the configuration pane.

  Key file

  Is the private key used for creating the client X.509 certificate in PEM format. This option is used together with a certificate for a non-trusted connection.

  Pass phrase

  Is the password used to unlock the key file. The value is needed only if the key file is encrypted.

  Label

  Identifies a certificate in the file if the file contains more than one certificate.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- Explicit. The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- Password Passthru. The user ID and password received from the client application are passed to the database, at connection time, for authentication.
Trusted. The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

Via MFD/Select Application

This option is used only for chained authentication. For details about this process, see How to Configure the Adapter for Chained Execution on page 1953.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default. If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

The user ID and password are explicitly specified for each connection, and are passed to the REST Web Service at connection time for authentication. The syntax is:

ENGINE REST SET CONNECTION_ATTRIBUTES connection_name/
[ user[,pswd]]:‘base_URL WADL_URL [AUTH:applid/mf]
[fieldname="value" ...]
[PROXYS: proxy_IP_address] [PROXYP: {80|port_number}]
[CERTIFICATE: cert_location [cert_key=key_file][cert_phrase=pass_phrase]
[cert_label= cert_label]]'

where:

REST

Indicates the adapter.

connection_name

Is the logical name used to identify this particular set of attributes.

user, pswd

If specified, the user ID and password are passed to the authentication operation defined in the AUTH parameter at connection time.

For chained authentication, these are required fields if defined in the authentication Master File, either in the header or in the groups description. For related information, see How to Configure the Adapter for Chained Execution on page 1953.
**base_URL**

Is the part of the URL that is common for calling all of the functionality of a particular RESTful Web Service.

**WADL_URL**

Is the URL of the WADL that describes the web service. This is used to create a synonym. If a WADL File is not used, this should be set to file://Fake_URL.wadl.

**applid/mf**

For chained authentication, this is the location on the server of the Master File that describes the associated authentication operation. For related information, see *How to Configure the Adapter for Chained Execution* on page 1953.

**fieldname=value**

For chained authentication in which you are passing additional parameters to an authentication operation, fieldname corresponds to the field defined with NEED_VALUE value in the ACCESSPROPERTY parameter of the Master File, except for fields using the USERNAME and PASSWORD reserved names.

For an illustration, see *How to Pass Additional Parameters to an Authentication Operation* on page 1956.

**Note:**

- Values provided in the SET CONNECTION_ATTRIBUTES command overwrite default values set in XDEFAULT parameter in the Master File.
- Field values must be enclosed in double quotation marks (") and cannot contain double or single quotation marks.

**proxy_IP_address**

Is the IP address of the proxy server, which intercepts requests and forwards them to the server.

**port_number**

Is the port number on which the proxy server listens. The default port number is 80.

**cert_location**

Is the location of locally-stored user-provided server x.509 certificates (Trusted CA) for SSL authentication. The certificate file is used to authenticate the server to which the adapter is connecting.
The trusted certificate file (trustedcertfile) points to a file of CA certificates in PEM format, as illustrated in the following example:

```
-----BEGIN CERTIFICATE-----
... (CA certificate in base64 encoding) ...
-----END CERTIFICATE-----
```

A trusted certificate file can contain several CA certificates. You can add text before, between, and after certificates. For example, to provide descriptions of certificates.

If you wish to specify a non-trusted certificate, enter the following additional information:

```
[cert_key=key_file] [cert_phrase=pass_phrase] [cert_label=cert_label]
```

where

- **key_file**
  
  Is the private key used for creating the client X.509 certificate in PEM format. This entry is required for a non-trusted connection.

- **pass_phrase**
  
  Is the password used to unlock the key file. This entry is needed only if the key file is encrypted.

- **cert_label**
  
  Identifies a certificate in the file if the file contains more than one certificate.

**Example:** **Declaring Connection Attributes Manually**

The following SET CONNECTION_ATTRIBUTES command allow the application to access the web application named GEONAMES.

```
ENGINE REST SET CONNECTION_ATTRIBUTES geonames/,:'http://api.geonames.org
file://Fake_URL.wadl'
```
Security for RESTful Web Services

**How to:**
Configure the Adapter for Chained Execution
Pass Additional Parameters to an Authentication Operation

**Example:**
Configuring Chained Authentication
Passing Additional Parameters to an Authentication Operation

Chained execution of an authentication operation is used when the web server returns a response containing a cookie or a token to be used in the subsequent processing operation. Chained execution is defined in the connection string associated with the requested operation. When a cookie is used, both connection strings (authentication and execution) must contain the same Base URL.

The Adapter for RESTful Web Services supports the following security facilities:

- Cookies, containing user credentials, which are in effect for the length of a TSCOM agent session (that is, between user connect and disconnect). The scope of the cookie is the single TSCOM agent. The received cookie is sent back to the sender IP, along with subsequent REST requests.

- Identification token values, which are returned by an authentication operation and are acceptable to associated execution operations.

Chained authentication supports the Explicit and Password Passthru (with PING capabilities) security models.

To use chained authentication, you must declare the connection for authentication, then create a Master File that contains the authentication specifications (using an authentication string), and store it in an application folder. You can then use the authentication metadata to create one or more associated execution connection strings.

**Note:** When the connection string contains user ID and password information, and chained authentication is not defined, basic HTTP authentication is used. That is, the user ID and password are encrypted using the x64 algorithm, and it is then used to establish the HTTP connection.
Procedure: How to Configure the Adapter for Chained Execution

To configure the adapter for chained authentication:

1. Create a connection string using a BASE URL needed for the REST call to authenticate. This connection is needed to specify the part of the REST URL that would prefix the URL Extension to the authentication operation.

   In the Connection Parameters pane of the Web Console or the Data Management Console, enter the BASE URL, and click Configure without Authentication.

   Keep in mind that if a cookie (rather than a token) is to be used in the subsequent processing operation, you must specify the same Base URL for this authentication connection string and for the execution connection string that you specify in step 3.

2. Create synonyms for relevant authentication operations.

   Create the synonym from the Web Console or the Data Management Console, then open the Synonym Editor to edit the synonym using the following guidelines.

   Authentication synonyms must include the following input fields:

   **USERNAME**
   
   The user ID value is taken from the connection string defining the operation to be executed.

   **PASSWORD**
   
   The password value is taken from the connection string defining the operation to be executed.

   Authentication synonyms may also include fields with the following access properties. The following fields must belong to segments describing the REST request:

   **ACCESS_PROPERTY=NEED_VALUE**
   
   Defines fields that provide additional parameters for an authentication operation. You can supply default values in XDEFAULT parameters. Values provided in the associated connection string overwrite the default values.

   There may be more than one such field.

   The following fields must belong to segments describing the REST response:

   **ACCESS_PROPERTY=AUTHRESP**
   
   Defines fields that describe the result of an authentication operation. Correct response values must be provided in the ACCEPT attribute (using the OR predicate if more than one value is acceptable). There may be more than one such field. The operation is considered invalid if at least one of the fields contains a non-acceptable value.
ACCESS_PROPERTY=AUTHTOKEN

Defines a field that contains a response token to be passed as an input value to the operation to be executed. There can be only one such field. If none is defined, the authentication operation is expected to return a cookie.

3. Create a connection string using a BASE URL that is used to call the execution request and a previously created authentication operation synonym.

In the Connection Parameters pane of the Web Console or the Data Management Console, enter the BASE URL, then from the Via MFD/Select Applications drop-down list, select the location on the server of the Master File that describes the associated authentication operation. Click Next and select the Master File that is used to run the authentication request.

4. In order to create synonyms for relevant execution operations, this must be done within a procedure. The reason is that Create Synonym runs a REST request to determine the response returned. The request must be authenticated properly to generate a valid response for use in creating the metadata.

For example:

- * Runs Authentication request
  EX WFLOGON
- * Runs a Create Synonym request
  CREATE SYNONYM rest/folderlist AT ibfs FOR ibfs/WFC/Repository
  PARMS 'HTTPMETHOD=GET PARAMSURL="IBIRS_action=get"'
  CHECKNAMES UNIQUENAMES DBMS REST DROP

5. Ensure that the operation synonyms have an input field that describes the authenticating token (if needed) using ACCESS_PROPERTY=AUTHTOKEN.

From the Web Console or the Data Management Console, open the Synonym Editor to edit the synonym as described.

For related information, see Connection Attributes for the Adapter for REST on page 1947 and Creating Synonyms on page 1957.

Example: Configuring Chained Authentication

Connection string:

ENGINE REST SET CONNECTION_ATTRIBUTES
ibfs/,:'http://localhost:8080/ibi_apps/rs file://Fake_URL.wadl
auth:rest/logon'
Master File fragment describing an authentication operation:

FILENAME=GETTOKEN, SUFFIX=REST, $  
SEGMENT=GETTOKEN, SEGTYPE=S0, $  
GROUP=HEADER, ALIAS=Header, ELEMENTS=2, $  
FIELDNAME=USERNAME, ALIAS=username, USAGE=A30, ACTUAL=A30,  
    ACCESS_PROPERTY=(NEED_VALUE), $  
FIELDNAME=PASSWORD, ALIAS=password, USAGE=A30, ACTUAL=A30,  
    ACCESS_PROPERTY=(NEED_VALUE), $  
FIELDNAME=__RESPONSE, USAGE=TX80L, ACTUAL=TX,  
    ACCESS_PROPERTY=(INTERNAL), $  
SEGMENT=RESPONSE, SEGTYPE=S0, SEGSUF=XML, PARENT=GETTOKEN,  
    POSITION=__RESPONSE, $  
FIELDNAME=RESPONSE, ALIAS=getToken0Out, USAGE=A1, ACTUAL=A1,  
    ACCESS_PROPERTY=(INTERNAL), $  
FIELDNAME=RESULT, ALIAS=Result, USAGE=A120, ACTUAL=A120,  
    ACCESS_PROPERTY=(AUTHTOKEN), REFERENCE=RESPONSE, PROPERTY=ELEMENT, $

Master File fragment describing a data retrieval operation:

FILENAME=FINDADDRESS, SUFFIX=REST, $  
SEGMENT=FINDADDRESS, SEGTYPE=S0, $  
GROUP=HEADER, ALIAS=Header, ELEMENTS=8, $  
FIELDNAME=HOUSENUMBER, ALIAS=houseNumber, USAGE=A30, ACTUAL=A30,  
    MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), XDEFAULT='2815', $  
FIELDNAME=STREET, ALIAS=street, USAGE=A30, ACTUAL=A30,  
    MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), XDEFAULT='PRAIRIE AVE.', $  
FIELDNAME=INTERSECTION, ALIAS=intersection, USAGE=A30, ACTUAL=A30,  
    MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $  
FIELDNAME=CITY, ALIAS=city, USAGE=A30, ACTUAL=A30,  
    MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), XDEFAULT='MIAMI BEACH', $  
FIELDNAME=STATE_PROV, ALIAS=state_prov, USAGE=A30, ACTUAL=A30,  
    MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), XDEFAULT='FL', $  
FIELDNAME=ZONE, ALIAS=zone, USAGE=A30, ACTUAL=A30,  
    MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), XDEFAULT='33140', $  
FIELDNAME=COUNTRY, ALIAS=country, USAGE=A30, ACTUAL=A30,  
    MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), XDEFAULT='US', $  
FIELDNAME=TOKEN, ALIAS=token, USAGE=A120, ACTUAL=A120,  
    ACCESS_PROPERTY=(NEED_VALUE, AUTHTOKEN), $  
FIELDNAME=__RESPONSE, USAGE=TX80L, ACTUAL=TX,  
    ACCESS_PROPERTY=(INTERNAL), $  
SEGMENT=RESPONSE, SEGTYPE=S0, SEGSUF=XML, PARENT=FINDADDRESS,  
    POSITION=__RESPONSE, $  
FIELDNAME=RESPONSE, ALIAS=findAddressResponse, USAGE=A1, ACTUAL=A1,  
    ACCESS_PROPERTY=(INTERNAL), $
**Syntax:**  

**How to Pass Additional Parameters to an Authentication Operation**

You can pass an extra set of parameters to the authentication operation using XDEFAULT parameters to set the default values in the appropriate Master File.

**Tip:** To complete this task, use the Synonym Editor in the Web Console or the Data Management Console.

A sample of the syntax is in the following example.

**Example:**  

**Passing Additional Parameters to an Authentication Operation**

```plaintext
directauthenticate DBID="HRADemo01" LANGID="1"

**Master File fragment:**

FILENAME=DIRECTAUTHENTICATE, SUFFIX=REST, $  
SEGMENT=DIRECTAUTHENTICATE, SEGTYPE=S0, $  
GROUP=HEADER, ALIAS=Header, ELEMENTS=4, $  
FIELDNAME=USERNAME, ALIAS=usrname, USAGE=A30, ACTUAL=A30,  
   ACCESSPROPERTY=(NEED_VALUE), $  
FIELDNAME=PASSWORD, ALIAS=pwd, USAGE=A30, ACTUAL=A30,  
   ACCESSPROPERTY=(NEED_VALUE), $  
FIELDNAME=DBID, ALIAS=dbId, USAGE=A30, ACTUAL=A30,  
   ACCESSPROPERTY=(NEED_VALUE), $  
FIELDNAME=LANGID, ALIAS=langId, USAGE=A30, ACTUAL=A30,  
   ACCESSPROPERTY=(NEED_VALUE), $  
   XDEFAULT='Test', $  
FIELDNAME=__RESPONSE, USAGE=TX80L, ACTUAL=TX,  
   ACCESSPROPERTY=(INTERNAL), $  
SEGMENT=RESPONSE, SEGTYPE=S0, SEGSUF=XML, PARENT=DIRECTAUTHENTICATE,

FIELDNAME=DIRECTAUTHENTICATERESULT, ALIAS=DirectAuthenticateResult,  
   USAGE=A5, ACTUAL=A5, ACCESSPROPERTY=(AUTHRESP), ACCEPT='true',  
   REFERENCE=RESPONSE, PROPERTY=ELEMENT, $  
```

1956 WebFOCUS
Managing RESTful Web Services Metadata

In this section:
Creating Synonyms

When the server accesses a RESTful Web Services provider, it needs to know how to pass parameters and accept responses for each REST request. In most RESTful Web Services, the Web Services provider documentation is used in determining the parameters to pass and the expected response. Therefore, the Create Synonym process sends a REST request including parameters to determine the response from the Web Service. A WADL (Web Application Description Language) file, which is in XML format, is sometimes used to define the request and response for each REST request.

Creating Synonyms

How to:
Create a Synonym

A synonym defines a unique logical name (also known as an alias) for each Web Services operation. Synonyms are useful because:

- They insulate client applications from changes to the location and identity of a request. You can move or rename a request without modifying the client applications that use it. You need make only one change, redefining the request synonym on the server.

- They provide support for the extended metadata features of the server, such as virtual fields and security mechanisms.

Creating a synonym generates a Master File and an Access File. These are metadata files that describe the Web Services request to the server.

Each synonym you create represents a single operation.

Note: Each synonym describes the Web Services operations of a particular provider. If the operation parameters are changed, the synonym must be recreated.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.

   The Applications page opens.
2. Click the *New* button and select *Synonym* from the drop-down menu.
The Adapter for Remote Servers allows applications to access data sources that reside on a remote server.

Using a mechanism called platform transparency, you can join data sources that reside on different platforms. The communication protocols used to connect to the servers may be the same or different.
Configuring Remote Servers

**How to:**
Declare Connection Attributes

**Reference:**
Connection Attributes for Remote Servers

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

**Procedure:**  **How to Declare Connection Attributes**
You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters* or from the Data Management Console, expand the *Adapters* folder. The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Click the *Remote Servers* link. The Remote Server Configuration pane displays basic parameters that are appropriate for the active protocol. If you wish to define connection parameters for services, click *Advanced* to expose additional connection options.

4. Enter values for the parameters required by the adapter as described in the connection attributes reference.

5. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

**Tip:** After you configure the remote server, you can test the connection by clicking the Remote Servers folder and selecting *Test* from the menu.

**Reference:**  **Connection Attributes for Remote Servers**
The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

**Basic**

**NODE**

8-character string
Defines the logical name of a node block, which must be unique in the file. The logical name can be a maximum of 8 characters, must begin with a letter, and can include any characters, except semicolon and equal sign. A node block contains keyword-value pairs, which are enclosed in a BEGIN-END statement. The following is an example of a node block:

```
NODE = ABC
BEGIN
  DESCRIPTION = client node block
  CLASS = CLIENT
  PROTOCOL = TCP
  HOST = localhost
  PORT = 8100
END
```

**HOST**

string

Defines the host that a client is connecting to or an IP address that a listener is listening on.

**PORT**

positive integer number

Defines the TCP port number that a client is connecting to or a listener is listening on.

**HTTP_PORT**

positive integer number

Defines the TCP port number on which the remote server’s Web Console listener is listening. Also used in declaring a communication block for the purpose of Remote Synonyms.

**CLASS**

If this is a z/OS server, you must include a qualifier.

**SECURITY**

Defines the authentication method used in communication to a remote server if no credentials are provided to the application.

- *PWP* for password passthrough authentication.
- *TRUSTED* for a trusted connection, where the current logged on user ID is passed to the server.
- *userid,password* where any value other than IWA, PWP or TRUSTED is considered a userid and password string for EXPLICIT authentication.

The information may be clear text or encrypted. Encrypting is automatic when the Web Console is used to set values.

Any ENGINE EDA SET CONNECTION_ATTRIBUTES server/userid,password command issued in a profile (server, group or user) or in a procedure overrides any value set by SECURITY = (including IWA, PWP, TRUSTED).

**DESCRIPTION**

`string`

Description for the server node.

**Advanced.** These options enable you to provide connection information for specific services.

**SERVICE NAME**

`CLIENT (servicename)`

Defines how to send outbound communications to a remote server.

servicename is optional. If provided, it must match the value of SERVICE in the service block of the server.

**HTTP_SSL**

0 or 1

Defines whether the Secure Sockets Layer protocol is used in the remote server Web Console listener:

- 0 if no SSL is used in the connection to the Web Console.
- 1 if SSL is used in the connection to the Web Console.

**COMPRESSION**

0 or 1

Activates data compression in a data transfer between client and server:

- 0 for no compression.
- 1 for compression on.

**ENCRYPTION**

0 or DES or Advanced or IBCRYPT

Defines the encryption method used in data transfer between client and server:

- 0 for no encryption.
- **DES** for 56-bit fixed-key Data Encryption Standard.
- **Advanced**, enables you to more easily select and combine ciphers, modes, and RSA key lengths. This option provides the following ciphers: 3DES, AES 128, AES192, AES 256; and the following modes: ECB and CBC.
- **IBCRIPT** for user-defined algorithm. The key is 512-bit RSA-encrypted.

**Note:** Only 0 and DES are supported for HTTP protocol.

**CONNECT_LIMIT**

number of seconds

Defines the maximum time that the client will wait for a TCP connection response from the server:

- -1 for indefinite wait.
- 0 for no wait.

**MAXWAIT**

Defines the time, in seconds, that the client will wait for a response from the server:

- -1 indicates an indefinite timeout.

### Managing Metadata for Remote Servers

In this section:

- Creating Synonyms
- Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the data types.
Creating Synonyms

**How to:**

Create a Synonym

**Example:**

Synonym for a Remote Data Source

Storing a Server Name in an Access File

Using a SUFFIX=EDA Synonym

Remote Multi-Segment Master and Access File

**Reference:**

Synonym Creation Parameters for Remote Servers

Managing Synonyms

Access File Keywords

Synonyms define unique names (or aliases) for each metadata description that is managed by the subserver. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access file that represent the server metadata.

You can use the Adapter for Remote Servers to create synonyms for remote data sources that reside on a subserver. If the data source is remote, the Master File contains the attribute SUFFIX=EDA.

**Note:** The Adapter for Remote Servers defines a relational data source, so its Master Files are single-segment. When a synonym is created from a multi-segment hierarchical table, like the CAR file, all its segments will be flattened out into one segment in the resulting Master File.

**Procedure:** How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   
   The Applications page opens.
2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:** You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

**Reference:** Synonym Creation Parameters for Remote Servers

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): tables, views, and any other supported objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.
Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Cardinality

Select the Cardinality check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Dynamic columns

To specify that the Master File created for the synonym should not contain column information, select the Dynamic columns check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select tables

Select tables for which you wish to create synonyms:

☑ To select all tables in the list, click the Select All button.
To select specific tables, select the corresponding check boxes.

**Example: Synonym for a Remote Data Source**

The following diagram illustrates the use of Master Files and Access Files for data sources. A synonym called SALES_EDA was created on a hub server using a SALES file located on a subserver.

- The multiple segments of the SALES file are flattened out in the SALES_EDA Master File, which is now a single-segment table.

- The SALES_EDA Master File contains SUFFIX=EDA to indicate that the data source is remote.

- The SALE_EDA Access File includes the synonym for the data source, the name of the data source, and the location of the data source:

  ```
  SEGNAME = SALES_EDA
  TABLENAME = SALES
  CONNECTION = SUBSRV1
  ```

  When you connect to the Hub Server, the SALES_EDA Master File and Access File are used to access the remote data source SALES, located on SUBSRV1.

  ![Diagram of data relationship]

  In the above Access File example, the value SUBSRV1 of the CONNECTION parameter must match an outbound node block in the Hub Server communications file.
Here's the original synonym on the sub-server:

**Sales.mas**

```plaintext
FILENAME=KSALES, SUFFIX=FOC , S
SEGMENT=STOR_SEG, SEGTYPE=S1, S
  FIELDDATE=STORE_CODE, ALIAS=SNO, USAGE=A3, S
  FIELDDATE=CITY, ALIAS=CTY, USAGE=A15, S
  FIELDDATE=AREA, ALIAS=LOC, USAGE=A1, S
$ $
SEGMENT=DATE_SEG, SEGTYPE=SH1, PARENT=STOR_SEG, S
  FIELDDATE=DATE, ALIAS=DTE, USAGE=A4MD, S
$ $
SEGMENT=PRODUCT, SEGTYPE=S1, PARENT=DATE_SEG, S
  FIELDDATE=PROD_CODE, ALIAS=PCODE, USAGE=A3, FIELDTYPE=I, S
  FIELDDATE=UNIT_SOLD, ALIAS=SOLD, USAGE=I5, S
  FIELDDATE=RETAIL_PRICE, ALIAS=RP, USAGE=D5.2M, S
  FIELDDATE=DELIVER_AMT, ALIAS=SHIP, USAGE=I5, S
  FIELDDATE=OPENING_AMT, ALIAS=INV, USAGE=I5, S
  FIELDDATE=RETURNS, ALIAS=RTN, USAGE=I3, MISSING=ON, S
  FIELDDATE=DAMAGED, ALIAS=BAD, USAGE=I3, MISSING=ON, S
```

Here's the synonym that is created by the Create Synonym utility:

**Sales_eda.mas**

```plaintext
FILENAME=SALES_EDA, SUFFIX=EDA , S
SEGMENT=SALES_EDA, SEGTYPE=S0, S
  FIELDDATE=STORE_CODE, ALIAS=STORE_CODE, USAGE=A3, ACTUAL=A3, S
  FIELDDATE=DATE, ALIAS=DATE, USAGE=A4MD, ACTUAL=A4MD, S
  FIELDDATE=PROD_CODE, ALIAS=PROD_CODE, USAGE=A3, ACTUAL=A3, S
  FIELDDATE=CITY, ALIAS=CITY, USAGE=A15, ACTUAL=A15, S
  FIELDDATE=AREA, ALIAS=AREA, USAGE=A1, ACTUAL=A1, S
  FIELDDATE=UNIT_SOLD, ALIAS=SOLD, USAGE=I5, ACTUAL=I4, S
  FIELDDATE=RETAIL_PRICE, ALIAS=RP, USAGE=D5.2M, ACTUAL=D8, S
  FIELDDATE=DELIVER_AMT, ALIAS=SHIP, USAGE=I5, ACTUAL=I4, S
  FIELDDATE=OPENING_AMT, ALIAS=INV, USAGE=I5, ACTUAL=I4, S
  FIELDDATE=RETURNS, ALIAS=RTN, USAGE=I3, ACTUAL=I4, MISSING=ON, S
  FIELDDATE=DAMAGED, ALIAS=BAD, USAGE=I3, ACTUAL=I4, MISSING=ON, S
```

**Sales_eda.acx**

```plaintext
SEGNAME=SALES_EDA, TABLENAME=EDADBA.sales, CONNECTION=server, KEYS=3, S
```

Notice not only is there no structure, but the three keys (STORE_CODE, DATE and PROD_CODE) were moved to the top.
Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
Option | Description
--- | ---
Data Management | Followed by these options, if applicable:

**Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)

**Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted.

**Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values.

**Reorganize.** Recreates the data source table preserving original data.

**Note:** This option is not available in the Web Console.

Impact Analysis | Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS* manual for details about Impact Analysis reports.

Copy | Copies the synonym to the clipboard.

Delete | Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.

Cut | Deletes the synonym and places it on the clipboard.

Properties | Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

**Reference:** Access File Keywords

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
</tbody>
</table>
**Keyword** | **Description**  
---|---
**TABLENAME** | Name of the table or view. This value can include a location or owner name as follows:  
\[
\text{TABLENAME}=[\text{location.}]\text{[owner.]}\text{tablename}
\]

**CONNECTION** | Indicates a previously declared connection. The syntax is:  
\[
\text{CONNECTION}=\text{connection}
\]
\[
\text{CONNECTION}=\text{''} \text{ indicates access to the local database server.}
\]
\[
\text{Absence of the CONNECTION attribute indicates access to the default database server.}
\]

**KEYS** | Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first \( n \) fields in the Master File segment.

**WRITE** | Specifies whether write operations are allowed against the table.

---

**Example:** **Storing a Server Name in an Access File**

The following example shows how to store the server name IBMSERVE in an Access File.

\[
\text{SEGNAME=}\text{ONE} , \text{TABLENAME=}\text{CAR} , \text{KEYS=}1 , \text{WRITE=}\text{YES} , \text{SERVER=}\text{IBMSERVE},$
\]

**Note:** Regardless of the type of data source to be accessed, the Access File must contain the following attributes:

- SEGNAME. The segment name in the Access File must match the segment name in the Master File.
- TABLENAME. This attribute specifies the name of the Master File on the server.
- SERVER. This attribute specifies the name of the server.

**Example:** **Using a SUFFIX=EDA Synonym**

The Master File of the synonym (DIGIT) on the server is:

\[
\text{FILENAME=}\text{DIGIT} , \text{SUFFIX=}\text{FOC},$
\]
\[
\text{SEGNAME=}\text{DIGIT} , \text{SECTYPE=}\text{S0},$
\]
\[
\text{FIELD=}\text{THIS\_DIGIT} , \text{THIS\_DIGIT} , I9 , I4 , \text{MISSING=}\text{ON},$
\]
\[
\text{FIELD=}\text{SSN} , \text{SSN} , A9 , A9 , \text{MISSING=}\text{ON},$
\]
\[
\text{FIELD=}\text{AMOUNT1} , \text{AMOUNT1} , P16.0 , P8 , \text{MISSING=}\text{ON},$
\]
\[
\text{FIELD=}\text{AMOUNT2} , \text{AMOUNT2} , P16.0 , P8 , \text{MISSING=}\text{ON},$
\]
The Master File of the synonym (DIGITEDA) on the client is:

```
FILENAME=DIGITEDA,SUFFIX=EDA,$
SEGNAME=DIGIT,SEGTYPE=S0,$
FIELD=THIS_DIGIT,THIS_DIGIT,I6,I4,$
FIELD=SSN,SSN,A9,A9,MISSING=OFF,$
FIELD=AMOUNT1,AMOUNT1,P8,P8,MISSING=ON,$
FIELD=AMOUNT2,AMOUNT2,P9.0,P8,MISSING=ON,$
```

The Access File of the synonym (DIGITEDA) on the client points to the file on the server:

```
SEGNAME=DIGIT,TABLENAME=DIGIT,KEYS=1,SERVER=PMSEDA,$
```

where:

- SEGNAME=DIGIT matches the segment name in the server Master File.
- TABLENAME=DIGIT specifies the name of the Master File on the server.
- SERVER=PMSEDA specifies the name of the server.

The EDACS3 client communication configuration file contains a NODE block that points to the server. For example:

```
NAME = EDA CLIENT USING CS/3 TCP/IP
NODE = PMSEDA
BEGIN
 ; TRACE = 31
 ; PROTOCOL = TCP
CLASS = CLIENT
HOST = IBIMVS ; DNS NAME (PNO 28109)
SERVICE = 2386 ; TCP/IP PORT FOR SERVER
END
```

The following requests (SQL and TABLE) reference the local Master File named DIGITEDA. As shown above, the corresponding Access File contains the server name and the Master File name, as it is known at the server. In this case, Server PMSEDA contains a Master File called DIGIT. At the server, the DIGIT Master File describes a FOCUS data source. The communications configuration file contains an entry for server name PMSEDA so that the FOCUS client can establish communications with the server.

<table>
<thead>
<tr>
<th>SQL request</th>
<th>TABLE request</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL SELECT * FROM DIGITEDA</td>
<td>TABLE FILE DIGITEDA</td>
</tr>
<tr>
<td>END</td>
<td>PRINT * END</td>
</tr>
</tbody>
</table>
**Note:** The name of an underlying physical file to which a SUFFIX=EDA Access File points must not start with a number. Using a number at the beginning of a file name:

- Will cause an error (FOC14069) when a request attempts to access data using a SUFFIX=EDA synonym that points to a file starting with a number.
- May cause problems when an external application (such as an API application) that does not accept files starting with numbers interacts with a SUFFIX=EDA synonym that points to a file starting with a number.
- May be problematic for a third-party application that does not work with numeric file names or with file names that start with numbers.

**Example:** Remote Multi-Segment Master and Access File

The following is a multi-segment Synonym. It describes two tables on the sub-server, JOBHIST and JOBLIST that are joined on the column JOBCLASS:

**Jobs_eda.mas**

FILENAME=jobs_eda, SUFFIX=EDA, $
SEGMENT=JOBHIST, SECTYPE=S0, $
   FIELDDESC=PIN, ALIAS=PIN, USAGE=A9, ACTUAL=A9, $
   FIELDDESC=JOBSTART, ALIAS=JOBSTART, USAGE=YMD, ACTUAL=DATE, $
   FIELDDESC=JOBCLASS, ALIAS=JOBCLASS, USAGE=A8, ACTUAL=A8, $
   FIELDDESC=FUNCTITLE, ALIAS=FUNCTITLE, USAGE=A20, ACTUAL=A20, $
SEGMENT=JOBLIST, SECTYPE=S0, PARENT=JOBHIST, $
   JOIN_WHERE=JOBHIST.JOBCLASS EQ JOBLIST.JOBCLASS;,$
   FIELDDESC=JOBCLASS, ALIAS=JOBCLASS, USAGE=A8, ACTUAL=A8,$
   FIELDDESC=CATEGORY, ALIAS=CATEGORY, USAGE=A25, ACTUAL=A25,$
   FIELDDESC=JOBDESC, ALIAS=JOBDESC, USAGE=A40, ACTUAL=A40,$
   FIELDDESC=LOWSAL, ALIAS=LOWSAL, USAGE=D12.2M, ACTUAL=D8,$
   FIELDDESC=HIGHSAL, ALIAS=HIGHSAL, USAGE=D12.2M, ACTUAL=D8,$
   FIELDDESC=GRADE, ALIAS=GRADE, USAGE=A2, ACTUAL=A2,$
   FIELDDESC=LEVEL, ALIAS=LEVEL, USAGE=A25, ACTUAL=A25,$

The following is the corresponding multi-segment Access File:

**Jobs_eda.acx**

SEGNAME=JOBHIST, TABLENAME=EDADBA.jobhist, CONNECTION=server,$
SEGNAME=JOBLIST, TABLENAME=EDADBA.joblist, CONNECTION=server,$

**Note:** While this synonym could not be created using the Web Console Create Synonym feature since it points to two different tables, it could be created in the Data Management Console using the Synonym Editor. Starting with a new synonym, each table is added using Insert > Segment via Metadata Import from the remote server. The JOIN_WHERE clause is automatically added to indicate the tables are joined on the JOBCLASS.
Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**
How to Override the Default Precision and Scale

ENGINE EDA SET CONVERSION RESET
ENGINE EDA SET CONVERSION format RESET
ENGINE EDA SET CONVERSION format [PRECISION precision [scale]]
ENGINE EDA SET CONVERSION format [PRECISION MAX]

where:

**EDA**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**
Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**
Is any valid format supported by the data source. Possible values are:

**INTEGER** which indicates that the command applies only to INTEGER columns.

**DECIMAL** which indicates that the command applies only to DECIMAL columns.

**REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
Example: Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

ENGINE EDA SET CONVERSION INTEGER PRECISION 7

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

ENGINE EDA SET CONVERSION FLOAT PRECISION 14 3

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

ENGINE EDA SET CONVERSION INTEGER RESET

The following example shows how to set the precision and scale attributes for all fields to the defaults:

ENGINE EDA SET CONVERSION RESET

Executing Stored Procedures

How to:

Execute a Stored Procedure Using Distributed Execution

Query Adapter Settings

In addition to making data available to the client, a server can store procedures, which are called remote procedures or stored procedures.

The CREATE SYNONYM (and/or DROP SYNONYM) command can be executed using a stored procedure on either the Hub or Full-Function Server.

Syntax: How to Execute a Stored Procedure Using Distributed Execution

You can execute stored procedures by issuing the command:

SQL EDA EX rpcnameparm1, parm2, ...
END

where:

rpcname

Is a procedure on the server.
*parm1, parm2,...*

Are character strings sent to the server (they are the same as parameters you can pass on the execution line of a FOCEXEC).

**Syntax:**  
**How to Query Adapter Settings**

To view the adapter parameter settings, issue the command:

```
SQL EDA ?
```

The output is:

```
> sql eda ?
(FOC1450) CURRENT EDA INTERFACE SETTINGS ARE :
(FOC1446) DEFAULT DBSPACE IS                  - : IBIEDA
(FOC1449) CURRENT SQLID IS                    - : USER1
(FOC1444) AUTOCLOSE OPTION IS                 - : ON FIN
(FOC1496) AUTODISCONNECT OPTION IS            - : ON FIN
(FOC1499) AUTOCOMMIT OPTION IS                - : ON COMMAND
(FOC1441) WRITE FUNCTIONALITY IS              - : OFF
(FOC1445) OPTIMIZATION OPTION IS              - : ON
(FOC1484) SQL ERROR MESSAGE TYPE IS           - : DBMS
(FOC1552) INTERFACE DEFAULT DATE TYPE         - : NEW
```
The Adapter for RMS allows applications to access RMS data sources. The adapter converts application requests into native RMS statements and returns answer sets to the requesting application. If the metadata is configured for read/write capabilities, it can insert data from an application into the data source.

You can also access compressed data sets with this adapter. However, the actual compression is done using the ZCOMP Exit. For details, see Data Set Compression Exit: ZCOMP on page 2795.

**Topics:**
- Preparing the RMS Environment
- Configuring the Adapter for RMS
- Managing RMS Metadata
- Manually Describing RMS Files
- Describing Complex RMS Keyed
- Associating an RMS Data Source to a Master File
- Retrieving Data From RMS Files
- Syntax for RMS Master File Attributes
- RMS Attribute Summary
- Read/Write Usage Limitations of the Adapter for RMS
Preparing the RMS Environment

RMS is a standard part of OpenVMS. Therefore, the standard release level for the Version of OpenVMS being used is the supported release level.

You can create metadata based on either CDD Repositories or COBOL File Descriptions. If you use CDDs, a proper RDB environment must be available. If RDB standard (of any version level) and CDDs are installed and available globally to all users, then no additional steps are required for CDD use.

Configuring the Adapter for RMS

**How to:**
Configure the Adapter

You can configure the Adapter for RMS from the Web Console or the Data Management Console.

**Procedure:**  **How to Configure the Adapter**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*.
   
   or

   From the Data Management Console, expand the *Adapters* folder.
   The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

**Note:** The RMS adapter is under the *Sequential and Indexed* group folder. No input parameters are required.
Managing RMS Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the RMS data types.

You can create metadata:

- By using the Create Synonym facility on the Web Console or the Data Management Console.
- By manually creating a Master File and Access File with a system editor.

Both methods describe data files to the server for OpenVMS with a Master and an Access File.

The Master File describes the type of data file you are using, the structure, and the fields it contains. The Access File provides a number of attribute parameters, including SHARED ACCESS to support READ/WRITE capabilities and an RMSFILE attribute, which offers one method for associating the data source with the Master File. For details about Access File uses, see When to Use an Access File With an RMS Data Source on page 2026.
Creating Synonyms

How to:
Create a Synonym

Example:
Creating a Synonym Using a COBOL File Description
Creating a Synonym Using CDD Record Definitions

Reference:
Synonym Creation Parameters for RMS
Managing Synonyms

Synonyms define unique names (or aliases) for each RMS table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms. Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.
2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.
3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.
4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.
5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.
The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.
- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:** **Synonym Creation Parameters for RMS**

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

**Select potential candidates for synonyms:**

**Synonym Candidates**

You can base your synonym on either CDD definitions or COBOL definitions. Choose one of these options from the drop-down list.

Next, you must specify the locations of either the CDD or COBOL definitions. Options vary depending on the selection you make here.

For related information about COBOL File Descriptions, see *Translating COBOL File Descriptions* on page 2773.

**For CDD definitions:**

**Location of CDDs**

If your repository is in a non-standard location (that is, one which is not declared by CDD$DEFAULT), you can supply the CDD location here.

If CDD$DEFAULT is declared, its current value appears in the input box, where you may leave it as is or change it.

**CDD name**

Type a filter for retrieving a partial list of CDD references (for example, those starting with V%).

You must supply filter values in uppercase characters, followed by a % sign. OpenVMS wildcards are not permitted.
For COBOL definitions:

**Directory Path**

Specify a full path directory name where the COBOL definitions are located. (Wild card characters are not permitted.)

For information about specific layout and syntax requirements, see *COBOL FD Syntax Requirements* on page 2794.

**File Name/File Extension**

If you wish to limit retrieval, you can type a file name and/or file extension:

- In the File name box, type a full name or a partial name with a wildcard symbol %. A full name returns just that entry. A name with a wildcard symbol may return many entries.
- In the File extension box, type an extension with or without the wildcard symbol %.

You must supply filter values in *uppercase* characters.

Location of RMS data files:

**Directory path**

Specify a full path directory name where RMS is located. This may be a logical that points to the full directory path or a directory path that uses a logical. OpenVMS wildcards are not allowed.

**File Name**

Type a filter for retrieving a partial list of RMS file names in the directory (for example, those starting with V%).

You must supply filter values in *lowercase* characters, followed by a % sign. OpenVMS wildcards are not allowed.

**File Extension**

Type a filter for retrieving a partial list of RMS files based on the file extensions within the directory.

The normal default for RMS files, dat%, is pre-populated in the input box and must not be changed if you wish to search for .dat files.

You can change the .dat value by specifying a filter to access files that do not use the RMS normal default (that is, those starting with rms%). You must supply filter values in *lowercase* characters, followed by a % sign. OpenVMS wildcards are not allowed.
Get Candidates button

Click this button to obtain the selection list of candidates for which synonyms can be created.

Select actual candidates for synonyms:

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Tip:** While you can change individual names in the list, entering a prefix or suffix enables you to make global changes that are particularly useful when many synonyms are being created.

An alternate method for dealing with duplicate names is to store them in separate application directories and change the application path as needed for a particular table.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

Set COBOL FD translation options

For a COBOL FD, optionally, select Customize COBOL FD conversion options to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see Customization Options for COBOL File Descriptions on page 2775.

Validate

Select the Validate check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See Validation for Special Characters and Reserved Words on page 2821 for more information.
When the Validate option is unchecked, only the following characters are converted to underscores: ';' '; ' ' "; '/'; '; ' '$'. No checking is performed for names.

**Make unique**

Select the Make unique check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

**For CDD definitions:**

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Select CDD records**

To select all CDD records in the list, select the check box to the left of the Default Synonym Name column heading.

To select specific records, select the corresponding check boxes.

**Associate records to physical files**

In the list of CDD objects and data files, use the pull-down menu on the right to associate the CDD record with the physical data file.

**For COBOL definitions:**

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Select COBOL records**

To select all COBOL records in the list, select the check box to the left of the Default Synonym Name column heading.

To select specific records, select the corresponding check boxes.

**Associate records to physical files**

In the list of COBOL objects and data files, use the pull-down menu on the right to associate the COBOL record with the physical data file.
Example: Creating a Synonym Using a COBOL File Description

To generate the following synonym from the Web Console or the Data Management Console Create Synonym panes:

1. On the first Create Synonym pane, select COBOL FD from the Synonym Candidate drop down list.
2. To specify the location of the COBOL FD, enter mydata:[RMS] as the Directory Path.
3. Leave the File Name field blank and accept the default extension, cbl, to filter the list of COBOL FDs.
4. Next, specify the location of the RMS data files. Enter mydata:[RMS] as the Directory Path.
5. Leave the File Name field blank and accept the default extension, dat.
6. Click the Get Candidates button.
7. The list of candidates is displayed on the second Create Synonym pane. Click the check box for rmscar.cbl in the first column.
8. To associate the selected candidate with a particular COBOL data file, choose rmscar.dat from the pull-down menu in the RMS data file column.
9. For this example, the default translation options are suitable, so leave the Customization options box unchecked.
10. Click the Create Synonym button.

The synonym is created and added under the specified application directory (baseapp is the default).

A status window displays the message: All Synonyms Created Successfully

11. From the message window, click Applications on the menu bar.
12. Open the baseapp application folder in the navigation pane and click the synonym rmscar.
13. Choose Edit as Text from the menu to view the generated Master File.
**Generated Master File:**

FILENAME=RMSCAR, SUFFIX=RMS
DATASET=TSCQDATA:[TSCQDATA.RMS]rmscar.dat, $SEGMENT=ROOT, SETYPE=S0, $
GROUP=ROOT, ALIAS=E2, USAGE=A62, ACTUAL=A62, $
GROUP=PRIMARYKEY, ALIAS=KEY, USAGE=A50, ACTUAL=A50, $
FIELDNAME=COUNTRY, ALIAS=E3, USAGE=A10, ACTUAL=A10, $
FIELDNAME=CAR, ALIAS=E4, USAGE=A16, ACTUAL=A16, $
FIELDNAME=MODEL, ALIAS=E5, USAGE=A24, ACTUAL=A24, $
FIELDNAME=BODYTYPE, ALIAS=E6, USAGE=A12, ACTUAL=A12, $
FIELDNAME=SEATS, ALIAS=E7, USAGE=I8, ACTUAL=I4, $
FIELDNAME=RETAIL_COST, ALIAS=E8, USAGE=I8, ACTUAL=I4, $
FIELDNAME=DEALER_COST, ALIAS=E9, USAGE=I8, ACTUAL=I4, $
FIELDNAME=SALES, ALIAS=E10, USAGE=I8, ACTUAL=I4, $

14. To see the Access File, choose *Edit Access File as Text*.

**Generated Access File:**

ACCESS=SHARED, $

---

**Example:**  **Creating a Synonym Using CDD Record Definitions**

To generate the following synonym from the Web Console or the Data Management Console Create Synonym panes:

1. On the first Create Synonym pane, select *CDD Definition* from the Synonym Candidate drop down list.
2. To specify the location of the CDDs, enter `mydata:[RMS.CDDPLUS]` as the Directory Path.
3. In the CDD Name field, enter R% to filter the list of CDD definitions. (Uppercase characters are required.)
4. Next, specify the location of the RMS data files. Enter `mydata:[RMS.CDDPLUS` as the Directory Path.
5. Click the *Get Candidates* button.
6. The list of candidates is displayed on the second Create Synonym pane. Click the check box for `rmscar` in the first column.
7. To associate the selected candidate with a particular CDD data file, choose `rmscar.dat` from the pull-down menu in the RMS data file column.
8. Click the *Create Synonym* button.

Tip: If you wish, you can choose a different data file at a later time using a FILEDEF, as described in *Associating an RMS Data Source to a Master File* on page 2023.
The synonym is created and added under the specified application directory (baseapp is the default).

A status window displays the message: *All Synonyms Created Successfully*

**9.** From the message window, click *Applications* on the menu bar.

**10.** Open the *baseapp* application folder in the navigation pane and click the synonym *rmscar*.

**11.** Choose *Edit as Text* from the menu to view the generated Master File.

**Generated Master File:**

```
FILENAME=RMSCAR, SUFFIX=RMS
DATASET=TSCQDATA:[TSCQDATA.RMS]rmscar.dat, $
SEGMENT=ROOT, SEGTYPE=S0, $
  GROUP=PRIMARYKEY, ALIAS=KEY, USAGE=A50, ACTUAL=A50, $
  FIELDNAME=COUNTRY, ALIAS=COUNTRY, USAGE=A10, ACTUAL=A10, $
  FIELDNAME=CAR, ALIAS=CAR, USAGE=A16, ACTUAL=A16, $
  FIELDNAME=MODEL, ALIAS=MODEL, USAGE=A24, ACTUAL=A24, $
  FIELDNAME=SEATS, ALIAS=SEATS, USAGE=P7, ACTUAL=I4, $
  FIELDNAME=RETAIL_COST, ALIAS=RCONST, USAGE=P7, ACTUAL=I4, $
  FIELDNAME=DEALER_COST, ALIAS=DCOST, USAGE=P7, ACTUAL=I4, $
  FIELDNAME=SALES, ALIAS=SALES, USAGE=P7, ACTUAL=I4, $
```

**12.** To see the Access File, choose *Edit Access File as Text*.

**Generated Access File:**

```
ACCESS=SHARED, $
```

**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>To update the synonym, it is strongly recommended that you use the graphical interface provided by the <em>Open</em> option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
</tbody>
</table>
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

### Manually Describing RMS Files

#### In this section:
- File Attributes
- Segment Attributes
- Field Attributes
- Describing Indexed Files (SUFFIX=RMS)
- Segment Name for Indexed Files
- Describing Keys
- Single-Field Secondary Keys

These topics outline the procedures necessary for manually describing RMS files.

#### File Attributes

#### In this section:
- FILENAME
- SUFFIX
- DATASET

File attributes are FILENAME, SUFFIX, and, optionally, DATASET, which name the file and describe the file type and data source location. For example:

FILENAME=LIBRARY1, SUFFIX=RMS, DATASET=mydata.DAT ,$
**FILENAME**

The FILENAME attribute is optional. It is recommended that you include the file name for documentation purposes. You can specify any name for this attribute, but you should use the same name that you give the Master File.

The syntax is

```
FILE[NAME] = name
```

where:

- `name` is any name of 1 to 8 characters.

**SUFFIX**

The SUFFIX attribute describes the type of data file it will read.

The syntax is:

```
SUFFIX = type
```

where:

- `type` is a suffix listed in the following table:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Suffix</th>
<th>Physical Access Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keyed (Indexed) or unkeyed RMS file</td>
<td>RMS</td>
<td><code>RMSFILE</code> in Access File or <code>DATASET</code> attribute in the Master File</td>
</tr>
<tr>
<td>Fixed-format sequential file</td>
<td>FIX</td>
<td><code>FILEDEF</code></td>
</tr>
<tr>
<td>Comma-delimited sequential file</td>
<td>COM</td>
<td><code>FILEDEF</code></td>
</tr>
</tbody>
</table>
The description of data and relationships between fields within a file is the same for keyed (indexed) RMS files, FIX (fixed-format sequential) files, and COM (comma-delimited) files, except for the following differences:

- Keyed (indexed) RMS uses the keyed RMS File System to access data using information in the Access File declarations. You can override the Access File declaration with a FILEDEF. For more information, see Associating an RMS Data Source to a Master File on page 2023. The others use sequential access using a FILEDEF to identify and access the file. The coding of FILEDEFs may be done locally within a procedure (before the access request), or within the EDASPROF.PRF if commonly accessed by multiple users.

- Index related declarations do not apply to fixed-sequential or comma-delimited files.

**DATASET**

DATASET is an optional attribute that specifies the physical location of the data source. It is used at the file declaration level of the Master File. The syntax is

```
{DATASET|DATA}='filename'
```

where:

- `filename`

  Is the platform-dependent physical name of the data source.

**Segment Attributes**

A Master File can be divided into segments, which are groups of fields that are related to one another. It is not always necessary to divide your file into segments.

Segment declarations identify and describe each segment in a file. They name the segments and indicate the relative positions in the file structure. In files with multiple record types, each record type will be described as a separate segment. Files with mixed singly- and multiply-occurring fields must also be described with separate segments defined for each type of occurrence. The attributes used to describe segments of different record types and multiply-occurring fields are described in Describing Multiple Record Types on page 2008 and in Describing Embedded Repeating Data on page 2014.

The following is an example of a segment declaration:

```
SEGNAME=BOOKINFO, PARENT=PUBINFO, SEGTYPE=S0,$
```
**SEGNAME**

Each segment declaration starts with the SEGNAME (or SEGMENT) attribute, which names the segment.

The syntax is

\{SEGNAME | SEGMENT\} = name

where:

name

Is a unique name of 1 to 8 characters.

**PARENT**

Files with more than one segment are defined as multi-segment structures.

Segments in a multi-segment structure have a parent/child relationship. Each segment, except the top or "root" segment, is the descendant of another segment called the "parent."

The PARENT attribute is used to identify a segment's parent segment. If no PARENT attribute is specified in the Master File, the default parent segment is the immediately preceding segment, except for the top segment, which has no parent.

The syntax is

PARENT = name

where:

name

Specifies a SEGNAME in the file.

For example:

...PARENT=PUBINFO...

**SEGTYP**

The SEGTYP attribute for RMS files is specified as S0.

The required syntax is:

SEGTYP=S0
Field Attributes

Field attributes describe the actual fields in each segment. Each field declaration consists of at least four attributes. They are:

FIELDNAME   ALIAS   USAGE   ACTUAL

For example:

FIELDNAME=PUBNO , ALIAS=PN , USAGE=A10 , ACTUAL=A10 ,$

There are also other optional attributes that can be used, such as DESCRIPTION, TITLE, and ACCEPT. DESCRIPTION enables you to include a description of the field. TITLE is the default report column title other than the field name. ACCEPT assigns a list or range of acceptable values to a field. ACCEPT is also used for RECTYPE values. These optional attributes are used by FOCUS, WebFOCUS, and various other client products. For further information about optional attributes, see the appropriate manuals.

FIELDNAME

Field names are unique names of 1 to 66 characters with the exception of indexes, which are limited to 12. The field name appears as a default column heading when you name the field in a report request. Field names may consist of any alphanumeric characters, but the first character must be a letter from A to Z. Field names may include embedded blanks, but it is not recommended, and you will need to enclose such a field name in single quotation marks (') if you reference the complete name (including the blank) in a request. Avoid using special characters (+ - $ * /() ' ; . , = and " > <), since they may cause confusion if the field is used in calculations.

The syntax is

FIELD[NAME] = name

where:

name

Meets the criteria described above.
**ALIAS**

_aliases are optional field names. Each field can have an alias to be used interchangeably with the field name. The length and format rules for field names apply to aliases. Aliases are not used as column titles.

The syntax is

```
ALIAS = alias
```

where:

- **alias**
  
  Is a name of 1 to 66 alphanumeric characters meeting the same criteria as for field names.

If you omit the alias, you must indicate its absence with either the following entry in the field declaration

```
ALIAS=,
```

or by holding its place with a comma delimiter (,):

```
FIELDNAME=PUBNO , ,USAGE=A10 ,ACTUAL=A10 ,$
```

**USAGE**

The **USAGE** attribute describes the way you want to use the field and display its values on reports. This attribute includes the data field type, display length, and any edit options that are to be applied when the field values are printed.

The syntax is

```
USAGE = usage
```

where:

- **usage**
  
  Describes the field in three parts: field type, field display length, and edit options.

The values that you specify for type and display length determine the number of print positions allocated for the field in any display or report. Edit options only affect printed or displayed fields; they are not active for extract files or other non-display retrievals.

The following table shows permissible **USAGE** field types and display lengths:

<table>
<thead>
<tr>
<th><strong>USAGE</strong></th>
<th><strong>Length</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1-9,095</td>
<td>Alphanumeric text</td>
</tr>
</tbody>
</table>
The following table shows edit options that may be applied to various A, D, F, I, or P usages:

<table>
<thead>
<tr>
<th>Edit Option</th>
<th>Meaning</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>Percent sign</td>
<td>Displays a percent sign along with numeric data. Does not calculate the percent.</td>
</tr>
<tr>
<td>B</td>
<td>Bracket negative</td>
<td>Encloses negative numbers in parentheses.</td>
</tr>
<tr>
<td>C</td>
<td>Comma suppress</td>
<td>Suppresses the display of commas. Used with numeric format options M and N (floating and non-floating dollar sign) and data format D (floating-point double-precision).</td>
</tr>
<tr>
<td>C</td>
<td>Comma edit</td>
<td>Inserts a comma after every third significant digit, or a period instead of a comma if continental decimal notation is in use.</td>
</tr>
<tr>
<td>DMY</td>
<td>Day-Month-Year</td>
<td>Displays alphanumeric or integer data as a date in the form day/month/year.</td>
</tr>
<tr>
<td>E</td>
<td>Scientific notation</td>
<td>Scientific notation Displays only significant digits.</td>
</tr>
<tr>
<td>L</td>
<td>Leading zeroes</td>
<td>Adds leading zeroes.</td>
</tr>
<tr>
<td>M</td>
<td>Floating $ (for US code page)</td>
<td>Places a floating dollar sign $ to the left of the highest significant digit.</td>
</tr>
</tbody>
</table>

**Note:** The currency symbol displayed depends on the code page used.
### Edit Option

<table>
<thead>
<tr>
<th>Edit Option</th>
<th>Meaning</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MDY</strong></td>
<td>Month-Day-Year</td>
<td>Displays alphanumeric or integer data as a date in the form month/day/year.</td>
</tr>
<tr>
<td><strong>N</strong></td>
<td>Fixed $(for US code page)</td>
<td>Places a dollar sign $ to the left of the field. The symbol displays only on the first detail line of each page.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The currency symbol displayed depends on the code page used.</td>
<td></td>
</tr>
<tr>
<td><strong>R</strong></td>
<td>Credit (CR) negative</td>
<td>Places CR after negative numbers.</td>
</tr>
<tr>
<td><strong>S</strong></td>
<td>Zero suppress</td>
<td>Zero suppress If the data value is zero, prints a blank in its place.</td>
</tr>
</tbody>
</table>

**Note:**

- Edit options can be specified in any order.
- The total length of the USAGE specification, including all edit options, may not exceed eight characters.
- Options M and N (floating and fixed dollar sign) both automatically imply option C (comma edit).
- Format type D (double-precision decimal number) implies option C.

The following table shows the various USAGE formats as they would be specified in a Master File. The USAGE formats contain type and length information as well as various edit options. The Value column shows the actual value as it would be read from the external file, and the Display column shows how the number would be displayed on a report.

<table>
<thead>
<tr>
<th>USAGE</th>
<th>Value</th>
<th>Display</th>
</tr>
</thead>
<tbody>
<tr>
<td>I7C</td>
<td>47693</td>
<td>47,693</td>
</tr>
<tr>
<td>D10.2S</td>
<td>0.00</td>
<td></td>
</tr>
<tr>
<td>P8.0CR</td>
<td>-4719</td>
<td>4,719 CR</td>
</tr>
<tr>
<td>F8.2MC</td>
<td>28148.00</td>
<td>$28,148.00</td>
</tr>
<tr>
<td>I5B</td>
<td>-341</td>
<td>(341)</td>
</tr>
</tbody>
</table>
**ACTUAL**

The ACTUAL attribute describes the type and length of your data as it actually exists in a file. The source of this information is the existing description of the file.

The syntax is

```
ACTUAL = actual
```

where:

*actual*

Is any of the format types listed in the following table:

<table>
<thead>
<tr>
<th>ACTUAL Type</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>An</td>
<td>Alphanumeric characters A to Z, 0 to 9, and other displayable ASCII characters, where ( n ) equals 1 to 4,095.</td>
</tr>
<tr>
<td>D8</td>
<td>Double-precision floating-point numbers stored internally in eight bytes (D_Floating).</td>
</tr>
<tr>
<td>F4</td>
<td>Single-precision floating-point numbers stored internally in four bytes (F_Floating).</td>
</tr>
<tr>
<td>ACTUAL Type</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------</td>
<td>------------</td>
</tr>
</tbody>
</table>
| $I_{n}$     | Binary integers:  
$I_{1}$ - Single-byte signed, binary integer (signed byte)  
$I_{2}$ - 2-byte signed, binary integer (signed word)  
$I_{4}$ - 4-byte signed, binary integer (signed longword)  
$I_{8}$ - 8-byte signed, binary integer (signed quadword)  
If an integer field contains an assumed decimal point (that is, if it is a scaled integer), represent the field as $I_{m}.n$, where $m$ is the total number of storage bytes, and $n$ is the number of decimal places. Therefore, $I_{4}.1$ means a 4-byte number with one decimal place.  
USAGE on a scaled integer should be minimally set up as a $P_{m+2}.n$.  
Octaword data types are not supported. |
| $P_{n}$     | Packed decimal format (packed numeric string) where $n$ is the number of bytes (1 to 16), each of which contains two digits, except for the last byte, which contains a digit and the sign. For example, $P_{6}$ means 11 digits plus a sign, packed two digits to the byte for the total of 6 bytes of storage. |
**ACTUAL Type** | **Definition**
---|---
$Z_n$ | Zoned decimal format (numeric string) where $n$ is the number of digits (1 to 31), each of which takes 1 byte of storage. The last byte contains a digit and the sign.

There are several standards for zoned data. For Read purposes, only right overpunched standards are supported and can be determined on Read since they are unique.

The specific format to use when writing data must be known for read/write purposes. The default is ASCII right overpunch. To change the default, you must edit the EDACONF [.BIN]EDAENV.COM file and add the following logical:

```plaintext
DEFINE /NOLOG IBI_ZONED_OUT_TYPE {1|2}
```

where:

1. Is the ASCII right overpunched standard (default).
2. Is the EBCDIC right overpunched standard.

Zoned right separate numeric or zoned left overpunched numeric formats are not supported. Zoned left separate is supported by using a $A_m+1$ ACTUAL and a numeric USAGE format.

**DATE**

DATE indicates that the field is an OpenVMS 64-bit datetime stamp. This usage also requires an A4 filler field immediately following in the Master File.

DATE/TIMESTAMP. Full OpenVMS date and timestamps are not directly supported. However, using a DEFINE in the Master File, you can declare a field as USAGE=A8, ACTUAL=A8, and then use the virtual (DEFINEd) field with HINPUT () and CVTSTIME () to support HDATE formats for output purposes.

The following conversions from ACTUAL format to USAGE (display) format are permitted:

<table>
<thead>
<tr>
<th>ACTUAL</th>
<th>USAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A, D, F, I, P, date format</td>
</tr>
<tr>
<td>D</td>
<td>D</td>
</tr>
</tbody>
</table>
The following table shows the USAGE and ACTUAL formats for COBOL, FORTRAN, PL1, and Assembler field descriptions.

<table>
<thead>
<tr>
<th>ACTUAL</th>
<th>USAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>date format</td>
</tr>
<tr>
<td>F</td>
<td>F</td>
</tr>
<tr>
<td>I</td>

* Equivalent to INTEGER in FORTRAN, FIXED BINARY(31) in PL/1, and F in Assembler.
** Equivalent to REAL in FORTRAN, FLOAT(6) in PL/1, and E in Assembler.
*** Equivalent to DOUBLE PRECISION or REAL*8 in FORTRAN, FLOAT(16) in PL/1, and D in Assembler.

**Note:**
- The USAGE lengths shown are minimum values. They may be larger if desired. Additional edit options may also be added.
- In USAGE formats, an extra character position is required for the minus sign if negative values are expected.
- PICTURE clauses are not permitted for internal floating-point items.
- USAGE length should allow for maximum possible number of digits.
- In USAGE formats, an extra character position is required for the decimal point.

**Describing Indexed Files (SUFFIX=RMS)**

RMS keyed (indexed) files may be described using a SUFFIX of RMS, an attribute called GROUP, and a FIELDTYPE of I to designate a key. The GROUP attribute designates a key that is comprised of one or more contiguous fields. Additional keys may be described using either the GROUP or FIELD attribute, and a FIELDTYPE of I.

**Segment Name for Indexed Files**

The segment name (SEGNAME value) of the first segment in an indexed file (SUFFIX=RMS) must be ROOT. The remaining segments can have any valid segment name. The only exception to this rule is for unrelated record types where the first segment name value must be DUMMY.

**Describing Keys**

The primary key is defined by the GROUP attribute and an alias value of KEY in the Master File. If there is a secondary key consisting of more than one field, it must also be described by the GROUP attribute and a numbered key. Otherwise, the secondary key can be indicated by using a FIELDTYPE of I in the field description.
The primary key of an RMS file is defined using the GROUP attribute, consisting of one or more fields. A file might only have one keyfield, but it must still be described with the GROUP declaration. The GROUP must contain ALIAS=KEY. Coding KEY without ALIAS= is not sufficient.

The GROUP declaration has the following syntax

```
GROUP=keyname, ALIAS=KEY, USAGE=usage, ACTUAL=actual,$
```

where:

- `keyname`
  - Is a name of 1 to 66 characters.

The secondary keys of an RMS file are indicated by using ALIAS=KEY(n) and FIELDTYPE=I in the GROUP or FIELD declaration for the key. For example

```
GROUP=keyname, ALIAS=KEYn, USAGE=usage, ACTUAL=actual, FIELDTYPE=I,$
```

where:

- `keyname`
  - Is a name of 1 to 48 characters.

- `KEYn`
  - Indicates the alternate key.

The first alternate key is designated as KEY1, the second as KEY2, and so on.

Alternatively, if the secondary key is made up of only one field, the following syntax can be used:

```
FIELD=keyname, ALIAS=KEYn, USAGE=usage, ACTUAL=actual, FIELDTYPE=I,$
```

**GROUP (for Contiguous Keys)**

Contiguous keys consist of adjacent fields.

The GROUP attribute is used to define a contiguous primary key or a secondary key that is comprised of more than one field. The syntax is

```
GROUP=groupname, ALIAS=KEY[n], USAGE=usage, ACTUAL=actual, FIELDTYPE=I,$
FIELD=fieldname, ALIAS=alias, USAGE=usage, ACTUAL=actual,$
```

where:

- `groupname`
  - Is a name of 1 to 48 characters.
KEY[n]
Indicates a contiguous key. Use only KEY to specify a primary key. Use KEY[n] to specify a secondary key, where n is a number from 1 to 254 that indicates the key reference number.

FIELDTYPE=I
Makes the key accessible for reporting and indicates that the key can be used for direct retrieval. Do not use FIELDTYPE=I for a primary key.

usage
Is the data type and length designation.

actual
Is the data type and length designation.

For example, consider the contiguous key in the first part of the following Master File:

FILENAME=MANUALS,SUFFIX=RMS,$
SEGMENT=ROOT,SEGTYPE=S0,$
GROUP=MDOCNUM        ,ALIAS=KEY  ,USAGE=A9      ,ACTUAL=A9      ,$
FIELDNAME=DOCNUM   ,ALIAS=DN   ,USAGE=A5      ,ACTUAL=A5      ,$
FIELDNAME=CODE     ,ALIAS=CD   ,USAGE=I6      ,ACTUAL=I4      ,$
FIELDNAME=MRELEASE ,ALIAS=MR   ,USAGE=A7      ,ACTUAL=A7      ,$
FIELDNAME=MPAGES   ,ALIAS=MP   ,USAGE=I5      ,ACTUAL=I2      ,$

GROUP (for Discontiguous Keys)
Discontiguous keys consist of non-adjacent fields. If the GROUP attribute is used with discontiguous keys, the syntax is

GROUP=groupname,ALIAS=DKEY[n],USAGE=usage,ACTUAL=actual,FIELDTYPE=I,$
FIELD=      ,ALIAS=alias ,USAGE=usage,ACTUAL=actual,$

where:

DKEY[n]
Indicates that this GROUP is the key layout for a discontiguous key. The GROUP declaration must explicitly specify ALIAS=DKEY. Use only DKEY to specify a primary key. Use DKEY[n] to specify a secondary key, where n is a number from 1 to 254 that indicates the key reference number.
**alias**

Is the name of the base field to which the discontiguous key field corresponds. Note that the field name for the key field must be blank.

**usage**

Is the data type and length designation.

**actual**

Is the data type and length designation.

**FIELDTYPE=1**

Makes the key accessible for reporting and indicates that the key can be used for direct retrieval. Do not use FIELDTYPE=1 for a primary key.

The fields that comprise the discontiguous key are described in the order in which they appear in the record. They are then re-described using the GROUP attribute. The order within the GROUP is determined by their order of significance within the discontiguous key.

For example, consider the discontiguous keys in the first part of the following Master File:

```plaintext
FILENAME=MANUALS,SUFFIX=RMS,$
SEGMENT=ROOT,SEGTYPE=S0,$
  FIELDNAME=DOCNUM  ,ALIAS=         ,USAGE=A5   ,ACTUAL=A5      ,$
  FIELDNAME=CODE     ,ALIAS=CD       ,USAGE=I6   ,ACTUAL=I4      ,$
  FIELDNAME=MRELEASE ,ALIAS=         ,USAGE=A7   ,ACTUAL=A7      ,$
  FIELDNAME=MPAGES   ,ALIAS=         ,USAGE=I5   ,ACTUAL=I2      ,$
GROUP=MANUALS_KEY   ,ALIAS=DKEY     ,USAGE=A12  ,ACTUAL=A12     ,$
  FIELDNAME=         ,ALIAS=DOCNUM   ,USAGE=A5   ,ACTUAL=A5      ,$
  FIELDNAME=         ,ALIAS=MRELEASE ,USAGE=A7   ,ACTUAL=A7      ,$
.
.
.
```

Note that within each segment, you can only have one instance of a key reference number. For example, consider the following: KEY5 and DKEY4 can be in the same segment because they do not reference the same key, but KEY4 and DKEY4 cannot be in the same segment because they reference the same key.

A GROUP of DKEY can occur only at the end of the segment, following all of the "real" field definitions since DKEY contains references to "real" fields as base fields.

**Note:** OCCURS segments cannot contain any key definitions. Non-OCCURS segments must contain either KEY or DKEY definitions.
**USAGE and ACTUAL**

For multi-field GROUPs, USAGE and ACTUAL formats are always alphanumeric. The ACTUAL attribute is An, where n is the sum of the actual lengths of the subordinate fields. The USAGE format is the sum of the internal storage lengths of the subordinate fields.

- Fields of USAGE I have an internal storage length of 4.
- Fields of USAGE F have an internal storage length of 4.
- Fields of USAGE P have an internal storage length of either 8 or 16.
- Fields of USAGE D have an internal storage length of 8.
- Alphanumeric fields have an internal storage length equal to the number of characters they contain as their field length. For example, fields of type An have an internal storage length of n.
- Natural date formats that are treated as integers have an internal storage length of 4.

For example, consider the discontiguous keys in a part of the following Master File:

```
FIELDNAME=FIELD1   ,ALIAS=         ,USAGE=P6   ,ACTUAL=P2      ,$
FIELDNAME=FIELD2   ,ALIAS=         ,USAGE=I9   ,ACTUAL=I4      ,$
FIELDNAME=FIELD3   ,ALIAS=         ,USAGE=A2   ,ACTUAL=A2      ,$
GROUP=ALTERNATE    ,ALIAS=DKEY     ,USAGE=A10  ,ACTUAL=A4      ,$
FIELDNAME=         ,ALIAS=FIELD3   ,USAGE=A2   ,ACTUAL=A2      ,$
FIELDNAME=         ,ALIAS=FIELD1   ,USAGE=P6   ,ACTUAL=P2      ,$
```

The GROUP declaration USAGE attribute tells how many positions to use for the group key. If this length is wrong, the group key will not be used correctly.

In this example, the lengths of the ACTUAL attributes for subordinate fields FIELD3 and FIELD1 total 4, which is the length of the ACTUAL attribute of the GROUP key. The lengths of the USAGE attributes for the subordinate fields total 8. However, the length of the GROUP key USAGE attribute is found by adding their internal storage lengths as specified by the field types: 2 for USAGE=A2 and 8 for USAGE=P6, for a total of 10.
Single-Field Secondary Keys

Single-field secondary keys must be described as fields with FIELDTYPE=I. The ALIAS must be the key reference number as described in the RMS File Description Language (FDL), that is, KEYn or DKEYn, where n is a number from 1 to 254. Secondary keys can be described as GROUPs if they consist of portions with dissimilar formats. For example,

FILENAME=CUST,SUFFIX=RMS,$
SEGNAME=ROOT,SEGTYPE=S0,$
   GROUP=G,ALIAS=KEY,USAGE=A10,ACTUAL=A10,$
   FIELDNAME=SSN,ALIAS=SSN,USAGE=A10,ACTUAL=A10,$
   FIELDNAME=FNAME,ALIAS=KEY1,USAGE=A10,ACTUAL=A10,FIELDTYPE=I,$
   FIELDNAME=LNAME,ALIAS=KEY2,USAGE=A10,ACTUAL=A10,FIELDTYPE=I,$

Here, SSN is a primary key and FNAME and LNAME are secondary keys.

If you are not sure of the secondary keys associated with a given file, you can use the OpenVMS ANALYSE facility. Refer to the OpenVMS documentation for ANALYSE/RMS. The DIRECTORY command with the /FULL qualifier will also show how many keys the file has.

Describing Complex RMS Keyed

In this section:

- Describing Multiple Record Types
- Using RECTYPE
- Describing Related Record Types
- Describing Unrelated Record Types
- Describing Embedded Repeating Data

These topics discuss various ways of describing complex RMS keyed files.

Describing Multiple Record Types

Files may have records that must be deciphered according to a record type indicator in the record itself. Describing these files involves two things. First, each different record type will need its own segment. Second, the relationship between the different record types (that is, between the different segments) will need to be determined and expressed using the PARENT attribute for each segment.
Using RECTYPE

The syntax for defining a RECTYPE field is

\[
\text{FIELDNAME=RECTYPE, ALIAS=alias, USAGE=usage, ACTUAL= actual, ]}, $,
\]

where:

**RECTYPE**
- Is the required field name.

**alias**
- Is the primary RECTYPE identifier. If there is an ACCEPT list or range, this value is any valid alias name.

**list**
- Is a list of one or more lines of specific RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the list is 255. Each item in the list must be separated by either a blank or the keyword OR. If an item in the list contains embedded blanks or commas, it must be enclosed within single quotation marks ('). The list may contain a single RECTYPE value.

For example:

\[
\text{FIELDNAME=RECTYPE, ALIAS=A, USAGE=A1, ACTUAL=A1, ACCEPT=A OR B OR C, $}
\]

**range**
- Is a range of one or more lines of RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the range is 255. If either value contains embedded blanks or commas, it must be enclosed in single quotation marks (').

To specify a range of values, include the lowest value, the keyword TO, and the highest value, in that order.

For example:

\[
\text{FIELDNAME=RECTYPE, ALIAS=100, USAGE=P3, ACTUAL=P2, ACCEPT=70 TO 100, $}
\]

When using an ACCEPT list or range, also called generalized RECTYPE, the RECTYPE field name is not unique across segments, therefore it must not be used in a WHERE clause of an SQL request. It is the responsibility of the client application to determine if the row for the RECTYPE is required. If the client application cannot do this, you must code individual segments for each RECTYPE.
To illustrate the use of the generalized RECTYPE capability in RMS file descriptions, consider the following record layouts in the DOC file. Record type DN is the root segment and contains the document number and title. Record types M, I, and C contain information about manuals, installation guides, and course guides, respectively. Notice that record types M and I have the same layout.

**Record Type DN:**

```
---KEY---
+-----------------------------------------------------------------+
DOCID    FILLER   RECTYPE   TITLE
+-----------------------------------------------------------------+
```

**Record Type M:**

```
-------KEY------
+-----------------------------------------------------------------+
MDOCID   MDATE   RECTYPE   MRELEASE            MPAGES     FILLER
+-----------------------------------------------------------------+
```

**Record Type I:**

```
-------KEY------
+-----------------------------------------------------------------+
IDOCID   IDATE   RECTYPE   IRELEASE            IPAGES     FILLER
+-----------------------------------------------------------------+
```

**Record Type C:**

```
-------KEY------
+-----------------------------------------------------------------+
CRSEDOC  CDATE   RECTYPE   COURSENUM   LEVEL   CPAGES     FILLER
+-----------------------------------------------------------------+
```

Without the ACCEPT attribute, each of the four record types must be described as separate segments in the Master File. For example, a unique set of field names must be provided for record type M and for record type I, although they have the same layout.
The generalized RECTYPE capability enables you to code just one set of field names that apply to the record layout for both record type M and record type I. The ACCEPT attribute can be used for any RECTYPE specification, even when there is only one acceptable value.

```
FILENAME=DOC, SUFFIX=RMS,$
SEGNAME=ROOT, SEGTYPE=S0,$
GROUP=DOCNUM, ALIAS=KEY, A5, A5,$
FIELD=DOCID, ALIAS=, A5, A5,$

FIELD=COURENUM, ALIAS=, A4, A4,$
FIELD=LEVEL, ALIAS=, A2, A2,$
FIELD=CPAGES, ALIAS=, I5, A5,$
FIELD=FILLER, ALIAS=, A7, A7,$
```

### Describing Related Record Types

Consider the LIBRARY file that contains three types of records, related by a combination of the key and the RECTYPE attribute. The ROOT records have a key that consists of the publisher’s number. The BOOKINFO segment has a key that consists of that same publisher’s number, plus a hard or soft-cover indicator. The SERIANO key consists of the first two elements, plus a record type.
In the sample file, the repetition of the publisher number interrelates the three types of records. The Master File for this file would look like the following:

FILENAME=LIBRARY6,SUFFIX=RMS,$
SEGNAME=ROOT,SEGTYPE=S0,$
GROUP=PUBKEY       ,ALIAS=KEY   ,USAGE=A10     ,ACTUAL=A10    ,$
FIELDNAME=PUBNO   ,ALIAS=PN    ,USAGE=A10     ,ACTUAL=A10    ,$
FIELDNAME=FILLER  ,ALIAS=      ,USAGE=A1      ,ACTUAL=A1     ,$
FIELDNAME=RECTYPE ,ALIAS=1     ,USAGE=A1      ,ACTUAL=A1     ,$
FIELDNAME=AUTHOR  ,ALIAS=AT    ,USAGE=A25     ,ACTUAL=A25    ,$
FIELDNAME=TITLE   ,ALIAS=TL    ,USAGE=A50     ,ACTUAL=A50    ,$
SEGNAME=BOOKINFO,SEGTYPE=S0,PARENT=ROOT,$
GROUP=BOINKEY     ,ALIAS=KEY   ,USAGE=A11     ,ACTUAL=A11    ,$
FIELDNAME=PUBNO1  ,ALIAS=P1    ,USAGE=A10     ,ACTUAL=A10    ,$
FIELDNAME=BINDING ,ALIAS=BI    ,USAGE=A1      ,ACTUAL=A1     ,$
FIELDNAME=RECTYPE ,ALIAS=2     ,USAGE=A1      ,ACTUAL=A1     ,$
FIELDNAME=PRICE   ,ALIAS=PR    ,USAGE=D8.2N   ,ACTUAL=D8     ,$
SEGNAME=SERIANO,SEGTYPE=S0,PARENT=BOOKINFO,$
GROUP=SERIKEY     ,ALIAS=KEY   ,USAGE=A12     ,ACTUAL=A12    ,$
FIELDNAME=PUBNO2  ,ALIAS=P2    ,USAGE=A10     ,ACTUAL=A10    ,$
FIELDNAME=BINDING1,ALIAS=B1    ,USAGE=A1      ,ACTUAL=A1     ,$
FIELDNAME=RECTYPE ,ALIAS=3     ,USAGE=A1      ,ACTUAL=A1     ,$
FIELDNAME=SERIAL  ,ALIAS=SN    ,USAGE=A15     ,ACTUAL=A15    ,$
SEGNAME=SYNOPSIS,SEGTYPE=S0,PARENT=ROOT,OCcURS=VARIABLE,$
FIELDNAME=PLOTLINE,ALIAS=PLOTL,USAGE=A10     ,ACTUAL=A10    ,$

A typical query might request information on price and call numbers for a specific publisher's number:

PRINT PRICE AND SERIAL BY PUBNO
IF PUBNO EQ 1234567890 OR 9876054321

Since PUBNO is part of the key, the retrieval can be made and the processing continues. For greater speed retrieval, you could add search criteria based on the BINDING field, which is also part of the key.

Describing Unrelated Record Types

A file may contain records that are not related to each other. Records with varying RECTYPEs exist independently of each other in a file, and the sequence of records in the file may be random.

Consider our LIBRARY file. Suppose that the file has three types of records: book information, magazine information, and newspaper information.

Since book information, magazine information, and newspaper information have nothing in common, these record types cannot be described in a parent/child relationship.
The records simply look like the following:

BOOK    MAGAZINE    NEWSPAPER

To describe a file with unrelated records, you must make the record types descendants of a root segment named DUMMY.

The following rules apply to the DUMMY segment:

- The root (top) segment name must be DUMMY.
- It can have only one field, with an empty FIELDNAME and ALIAS.
- Both its USAGE and ACTUAL attributes must be A1.

All of the other segments must be descendants of the DUMMY segment.

The Master File for this file would look like the following:

FILENAME=LIBRARY3, SUFFIX=FIX,$
SEGMENT=DUMMY,SEGTYPE=S0,$
   FIELDNAME=,ALIAS=,USAGE=A1,ACTUAL=A1,$
SEGMENT=BOOK,SEGTYPE=S0,PARENT=DUMMY,$
   FIELDNAME=RECTYPE,ALIAS=B,USAGE=A1,ACTUAL=A1,$
   GROUP=PUBNUM,ALIAS=KEY,USAGE=A10,ACTUAL=A10,$
   FIELDNAME=PUBNO,ALIAS=PN,USAGE=A10,ACTUAL=A10,$
   FIELDNAME=AUTHOR,ALIAS=AT,USAGE=A25,ACTUAL=A25,$
   FIELDNAME=TITLE,ALIAS=TL,USAGE=A50,ACTUAL=A50,$
   FIELDNAME=BINDING,ALIAS=BI,USAGE=A1,ACTUAL=A1,$
   FIELDNAME=PRICE,ALIAS=PR,USAGE=D8.2N,ACTUAL=D8,$
   FIELDNAME=SERIAL,ALIAS=SN,USAGE=A15,ACTUAL=A15,$
   FIELDNAME=SYNOPSIS,ALIAS=SY,USAGE=A150,ACTUAL=A150,$
SEGMENT=MAGAZINE,SEGTYPE=S0,PARENT=DUMMY,$
   FIELDNAME=RECTYPE,ALIAS=M,USAGE=A1,ACTUAL=A1,$
   FIELDNAME=PER_NAME,ALIAS=NA,USAGE=A50,ACTUAL=A50,$
   FIELDNAME=PER_DATE,ALIAS=DT,USAGE=YYMD,ACTUAL=YYMD,$
   FIELDNAME=,ALIAS=FILLER,USAGE=A4,ACTUAL=A4,$
SEGMENT=NEWSPAP,SEGTYPE=S0,PARENT=DUMMY,$
   FIELDNAME=RECTYPE,ALIAS=N,USAGE=A1,ACTUAL=A1,$
   FIELDNAME=NEW_NAME,ALIAS=NN,USAGE=A50,ACTUAL=A50,$
   FIELDNAME=NEW_DATE,ALIAS=ND,USAGE=I5MDY,ACTUAL=I5MDY,$
   FIELDNAME=,ALIAS=FILLER,USAGE=A4,ACTUAL=A4,$
   GROUP=PAPVI,ALIAS=KEY,USAGE=A4,ACTUAL=A4,$
   FIELDNAME=NVOL_NO,ALIAS=NV,USAGE=I2,ACTUAL=I2,$
   FIELDNAME=NISSUE,ALIAS=NI,USAGE=I2,ACTUAL=I2,
Describing Embedded Repeating Data

Some records may contain embedded repeating data. Consider the following record layout:

A   B   C1   C2   C1   C2

Fields C1 and C2 repeat within this data record. C1 has an initial value, as does C2. C1 then provides a second value for that field, as does C2. Thus, there are two values for fields C1 and C2 for every one value for fields A and B.

The number of times C1 and C2 occur does not have to be fixed, depending on the value of a counter field. Suppose field B is this counter field. In the case shown above, the value of field B is 2, since C1 and C2 occur twice. The value of field B in the next record may be different, and fields C1 and C2 will occur that number of times.

The number of times fields C1 and C2 occur can also be variable. In this case, everything after fields A and B is assumed to be a series of C1s and C2s, alternating to the end of the record.

You describe these multiply occurring fields by placing them in a separate segment. Fields A and B are placed in the first segment, called the root segment. Fields C1 and C2, which occur multiple times in relation to A and B, are placed in a descendant segment. You use an additional segment attribute, the OCCURS attribute, to specify that this segment is a multiply occurring segment.

Repeating fields or groups of fields described by the OCCURS attribute are not supported for free-format (comma-delimited) sequential files.

OCCURS

Example:

Using the OCCURS Attribute
Describing Parallel and Nested Sets of OCCURS Segments

The OCCURS attribute is an optional segment attribute used to describe records containing repeating fields or groups of fields. You define such records by describing the singly occurring fields in one segment and the multiply occurring fields in another, subordinate segment. The OCCURS attribute appears in the declaration for the subordinate segment.
The syntax is

\[
\text{OCCURS} = \{n | \text{fieldname} | \text{VARIABLE}\},$
\]

where:

\(n\)

Is an integer value showing the number of occurrences (1 to 4095).

\(\text{fieldname}\)

Names a data field in the parent segment, that is, a counter specifying the number of occurrences of the descendant segment.

\(\text{VARIABLE}\)

Indicates that the number of occurrences varies from record to record. The number of occurrences is computed from the record length (that is, if the field lengths for the segment add up to 40, and 120 characters are read in, it means there are three occurrences).

When different types of records are combined in one file, each record type can contain only one segment (defined as OCCURS=VARIABLE). It may have OCCURS descendants (if it contains a nested group), but it may not be followed by any other segment with the same parent, that is, there can be no other segments to its right in the structure. This restriction is necessary to ensure that data in the record is interpreted correctly.

**Example:** Using the OCCURS Attribute

You place the OCCURS attribute in the segment declaration after the PARENT attribute.

Consider the following record layout:

\[A \ B \ C1 \ C2 \ C1 \ C2\]

You have two occurrences of fields C1 and C2 for every one occurrence of fields A and B. Thus, to describe this file, you place fields A and B in the root segment, and fields C1 and C2 in the descendant segment.

You describe this file with the following Master File:

\[
\text{FILENAME=}\text{EXAMPLE1}, \text{SUFFIX=}\text{RMS},$
\]

\[
\text{GROUP=}\text{ONE} , \text{ALIAS=}\text{KEY} , \text{USAGE=}\text{A2} , \text{ACTUAL=}\text{A2} , \text{FIELDTYPE=}I ,$
\]

\[
\text{FILENAME=}\text{A} , \text{ALIAS=} , \text{USAGE=}\text{A2} , \text{ACTUAL=}\text{A2} ,$
\]

\[
\text{FILENAME=}\text{B} , \text{ALIAS=} , \text{USAGE=}\text{A1} , \text{ACTUAL=}\text{A1} ,$
\]

\[
\text{SEGNAME=}\text{TWO}, \text{PARENT=}\text{ONE}, \text{OCCURS=}2, \text{SEGTYPE=}S0,$
\]

\[
\text{FILENAME=}\text{C1} , \text{ALIAS=} , \text{USAGE=}\text{I4} , \text{ACTUAL=}\text{I2} ,$
\]

\[
\text{FILENAME=}\text{C2} , \text{ALIAS=} , \text{USAGE=}\text{I4} , \text{ACTUAL=}\text{I2} ,$
\]
**Note:** OCCURS is not supported for Write Access. However, if the fields occur a specific number of times, an alternate Master File can be built with the fields described that number of times (for example, PAYMENT_1, PAYMENT_2 if Payment occurs two times). Using the alternate Master, specific instances of the OCCURS can be referenced. If the OCCURS segments will not be referenced during the write, the alternate Master is not needed. However, the message (FOC1305) RMS Duplicate Record will display.

**Example:** Describing Parallel and Nested Sets of OCCURS Segments

You can have several sets of repeating fields in your data structure. You describe each of these sets of fields as a separate segment in your Master File.

Sets of repeating fields can be divided into two basic types: parallel and nested. Parallel sets of repeating fields are unrelated (that is, they have no parent/child or logical relationship). Consider the following record layout:

```
A1  A2  B1  B2  B1  B2  C1  C2  C1  C2  C1  C2
```

In this example, fields B1 and B2 and fields C1 and C2 repeat within the record. The number of times that fields B1 and B2 occur is unrelated to the number of times fields C1 and C2 occur. Fields B1 and B2 and fields C1 and C2 are parallel sets of repeating fields. They should be described in the Master File as children of the same parent, the segment that contains fields A1 and A2. The following Master File illustrates this relationship:

```
FILENAME=EXAMPLE1, SUFFIX=RMS,$
GROUP=ONE   ,ALIAS=KEY   ,USAGE=A2   ,ACTUAL=A2   ,FIELDTYPE=I   ,$
FIELDNAME=A1,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,   $
FIELDNAME=A2,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,   $
SEGNAME=TWO, SEGTYPE=S0, PARENT=ONE,  OCCURS=2,    $
FIELDNAME=B1,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,   $
FIELDNAME=B2,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,   $
SEGNAME=THREE, SEGTYPE=S0, PARENT=ONE,  OCCURS=3,    $
FIELDNAME=C1,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,   $
FIELDNAME=C2,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,   $
```

Nested sets of repeating fields are those whose occurrence in some way depends on one another. Consider the following data structure:

```
A1  A2  B1  B2  C1  C1  B1  B2  C1  C1  C1
```

2016 WebFOCUS
In this example, field C1 occurs after fields B1 and B2 occur once. Field C1 occurs a varying number of times, as recorded by a counter field, B2. There will not be a set of occurrences of C1 unless C1 is preceded by an occurrence of fields B1 and B2. Fields B1, B2, and C1 are a nested set of repeating fields. The following Master File illustrates this relationship:

FILENAME=EXAMPLE2, SUFFIX=RMS,$
GROUP=ONE   ,ALIAS=KEY   ,USAGE=A2   ,ACTUAL=A2   ,FIELDTYPE=I   ,$
    FIELDNAME=A1,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,      $
    FIELDNAME=A2,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,      $
SEGNAME=TWO,      SEGTYPE=S0, PARENT=ONE, OCCURS=2,     $
    FIELDNAME=B1,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,      $
    FIELDNAME=B2,   ALIAS= ,   USAGE=I6,   ACTUAL=I4,      $
SEGNAME=THREE,    SEGTYPE=S0, PARENT=TWO, OCCURS=B2,    $
    FIELDNAME=C1,   ALIAS= ,   USAGE=A2,   ACTUAL=A2,      $

Since field C1 repeats with relation to fields B1 and B2, which repeat in relation to fields A1 and A2, field C1 is described as a separate, descendant segment of Segment TWO, which is in turn a descendant of Segment ONE.

The following data structure contains both nested and parallel sets of repeating fields:

A1 A2 B1 B2 C1 C1 C1 B1 B2 C1 C1 C1 D1 D1 E1 E1 E1 E1

You describe this with the Master File that follows. The PARENT attribute is used to describe the logical relationship of the segments. Note that the assignment of the PARENT attribute shows you how the occurrences are nested:

FILENAME=EXAMPLE3,SUFFIX=RMS,$
GROUP=ONE   ,ALIAS=KEY   ,USAGE=A2   ,ACTUAL=A2   ,FIELDTYPE=I   ,$
    FIELDNAME=A1   ,ALIAS=   ,USAGE=A2   ,ACTUAL=A2   ,   $
    FIELDNAME=A2   ,ALIAS=   ,USAGE=I4   ,ACTUAL=I1   ,   $
SEGNAME=TWO,PARENT=ONE,OCCURS=2,SEGTYPE=S0,            $
    FIELDNAME=B1   ,ALIAS=   ,USAGE=A15  ,ACTUAL=A15  ,   $
    FIELDNAME=B2   ,ALIAS=   ,USAGE=I4   ,ACTUAL=I1   ,   $
SEGNAME=THREE,PARENT=TWO,OCCURS=B2,SEGTYPE=S0,         $
    FIELDNAME=C1   ,ALIAS=   ,USAGE=A25  ,ACTUAL=A25  ,   $
    FIELDNAME=FOUR,PARENT=ONE,OCCURS=A2,SEGTYPE=S0,      $
    FIELDNAME=D1   ,ALIAS=   ,USAGE=A15  ,ACTUAL=A15  ,   $
SEGNAME=FIVE,PARENT=ONE,OCCURS=VARIABLE,SEGTYPE=S0,    $
    FIELDNAME=E1   ,ALIAS=   ,USAGE=A5   ,ACTUAL=A5   ,   $
Note:

- Segments ONE, TWO, and THREE represent a nested group of repeating segments. Fields B1 and B2 occur a fixed number of times, so OCCURS equals 2. Field C1 occurs a certain number of times within each occurrence of fields B1 and B2. The number of times C1 occurs is determined by the value of B2, which is a counter. The value of B2 is 3 for the first occurrence of Segment TWO, and 4 for the second occurrence.

- Segments FOUR and FIVE consist of fields that repeat independently within the parent segment. They have no relationship to each other or to Segment TWO except for the common parent, so they represent a parallel group of repeating segments.

- As in the case of Segment THREE, the number of times Segment FOUR occurs is determined by a counter in its parent, A2. In this example, the value of A2 is 2.

- The number of times Segment FIVE occurs is VARIABLE. The rest of the fields in the record (all those to the right of the first occurrence of E1) as occurrences of E1. To ensure that data in the record is interpreted correctly, a segment defined as OCCURS=VARIABLE must be at the end of the record. In a data structure diagram, it will be the right-most segment. There can only be one segment defined as OCCURS=VARIABLE for each parent.

POSITION

The POSITION attribute is an optional attribute. It is used to describe a record in which non-repeating data follows embedded repeating data.

You describe the file as a multi-segment structure, made up of a parent segment and at least one child segment that contains the embedded repeating data. The parent segment is made up of whatever singly occurring fields are in the record, as well as an alphanumeric field (or fields) that indicates where the embedded repeating data appear in the record. The alphanumeric field is a placeholder that is the exact length of the combined embedded repeating data. For example, if you have four occurrences of an 8-character field, the length of the placeholder in the parent segment will be 32 characters.

The POSITION attribute is described in the child segment. It gives the name of the placeholder field in the parent segment.

The syntax is

```
POSITION = fieldname
```

where:

```
fieldname
```

Is the name of the field in the parent segment that defines the starting position of the multiply occurring fields.
Consider the following record layout:

A1 Q1 Q1 Q1 Q1 A2 A3 A4

In this example, field Q1 repeats four times in the middle of the record. When you describe this structure, you specify a field that occupies the position of the four Q1 fields in the record. You then assign the actual Q1 fields to a descendant, multiply occurring segment. The POSITION attribute, specified in the descendant segment, gives the name of the place holder field in the parent segment.

The Master File for this file would look like this:

FILENAME=EXAMPLE3,SUFFIX=RMS,$
GROUP=ONE   ,ALIAS=KEY   ,USAGE=A2   ,ACTUAL=A2   ,FIELDTYPE=I   ,$
FIELDNAME=A1     ,ALIAS=   ,USAGE=A2  ,ACTUAL=A2   ,$
FIELDNAME=QFIL   ,ALIAS=   ,USAGE=A1   ,ACTUAL=A32   ,$
FIELDNAME=A2     ,ALIAS=   ,USAGE=I2   ,ACTUAL=I2    ,$
FIELDNAME=A3     ,ALIAS=   ,USAGE=A10  ,ACTUAL=A10   ,$
FIELDNAME=A4     ,ALIAS=   ,USAGE=A15  ,ACTUAL=A15   ,$
SEGNAME=TWO,SEGTYPE=S0,PARENT=ONE,POSITION=QFIL,OCCURS=4,$
FIELDNAME=Q1     ,ALIAS=   ,USAGE=D8    ,ACTUAL=D8    ,$

If the total length of the multiple occurrences of the field(s) is greater than 256, you can use a filler field after the place holder field to make up the remaining length. This is because the format of a field cannot exceed 256 bytes.

This structure will only work if you have a fixed number of occurrences of the repeating field. This means that the OCCURS attribute of the descendant segment must be of the type OCCURS=\( n \). The following will not work: OCCURS=\( fieldname \) or OCCURS=VARIABLE.

When a segment is coded with ...OCCURS=\( n \), POSITION=\( fieldname \), ..., all segments that follow using OCCURS=\( n \) or OCCURS=\( fieldname \), must use the POSITION attribute to correctly map data.

**ORDER Field**

**How to:**

Describe Repeating Groups Depending on a Preceding Record Type Indicator Using MAPFIELD/MAPVALUE

**Example:**

Describing Repeating Embedded Data With Record Type Indicators

In an OCCURS segment, the order of the data may be significant. For example, the numbers may represent monthly or quarterly data, but the record itself may not explicitly specify the month (or quarter) to which the data applies.
You can add a special ORDER field to your Master File to identify the individual occurrences of data uniquely within their parent segment. This is typically done to the screen by the occurrence number versus a field value (for example, the month is 12). The sequence number of each instance of the segment is automatically defined as a virtual field, and does not actually exist within the file.

The following syntax rules apply to the ORDER field:

- It must be the last field described in an OCCURS segment. If you are using MAPVALUE, then MAPVALUE must be the last field preceded by the ORDER field.
- The field name is arbitrary.
- The ALIAS attribute must be ORDER.
- The USAGE attribute must be I\textsuperscript{n}, with any appropriate edit options; "$n" is a number from 1 to 9.
- The ACTUAL attribute must be I4.

For example:

\begin{verbatim}
FIELD=ACT_MONTH, ALIAS=ORDER, USAGE=I2, ACTUAL=I4, $
\end{verbatim}

Order values are assigned sequentially (1,2,3,...) and the order value is reset to 1 when a new instance of the parent segment is retrieved. The value is assigned prior to any selection tests that might accept or reject the record, and can be used in a screening condition. For example, to obtain data for the month of June, type:

\begin{verbatim}
SUM AMOUNT...
IF ORDER IS 6
\end{verbatim}

**Example:** Describing Repeating Embedded Data With Record Type Indicators

If a file contains records that have repeating embedded data, the OCCURS attribute is used to describe a separate segment for the repeating fields. In some files, however, the repeating fields themselves must be identified according to a record type indicator. Suppose you want to describe a file that, schematically, looks like the following:

\begin{verbatim}
A  Rectype B C     Rectype  B C 
A  Rectype D       Rectype  D
\end{verbatim}

You would need to describe three segments in your Master File, with A as the root segment, and segments for B, C, and D, as two descendant OCCURS segments for A.
This is its Master File:

```
FILE=ABCD, SUFFIX=RMS,$
GROUP=ONE, ALIAS=KEY, ACTUAL=A2, USAGE=A2,$
FIELDNAME=A, ALIAS=, USAGE=A2, ACTUAL=A2,$
SEGNAME=BC_SEG, SEGTYPE=S0, PARENT=ONE, OCCURS=2,$
FIELDNAME=RECTYPE, ALIAS=1, USAGE=I2, ACTUAL=I2,$
FIELDNAME=B, ALIAS=, USAGE=A5, ACTUAL=A5,$
FIELDNAME=C, ALIAS=, USAGE=A5, ACTUAL=A5,$
SEGNAME=D_SEG, SEGTYPE=S0, PARENT=ONE, OCCURS=2,$
FIELDNAME=RECTYPE, ALIAS=2, USAGE=I2, ACTUAL=I2,$
FIELDNAME=D, ALIAS=, USAGE=A15, ACTUAL=A15,$
```

Each of the two descendant OCCURS segments in this example depends on the record type indicator that appears for each occurrence.

All the rules of syntax for using RECTYPE fields and OCCURS segments apply to RECTYPEs within OCCURS segments.

Since the OCCURS segment depends on the RECTYPE indicator for its evaluation, the RECTYPE must appear at the start of each OCCURS segment. This allows very complex files to be described, including those with nested and parallel repeating groups that depend on RECTYPEs. For example:

```
A Rectype B C Rectype D Rectype D Rectype E Rectype E
```

In this case, B/C, and D represent a nested repeating group, and E represents a parallel repeating group.

**Syntax:**

**How to Describe Repeating Groups Depending on a Preceding Record Type Indicator Using MAPFIELD/MAPVALUE**

MAPFIELD is assigned as the ALIAS of the field that will be the record type indicator. You can give this field any name; it is otherwise described according to the usual syntax:

```
FIELD=name, ALIAS=MAPFIELD, USAGE=usage, ACTUAL=actual,$
```

The descendant segments, whose values depend on the value of the MAPFIELD, are described as separate segments, one for each possible value of MAPFIELD, and all descending from the segment that has the MAPFIELD. A special field, MAPVALUE, is described as the last field in these descendant segments. If an ORDER field is chosen, it must be used before the MAPVALUE. The actual MAPFIELD value is supplied as the MAPVALUE ALIAS.

The syntax is

```
FIELDNAME=MAPVALUE, ALIAS=alias, USAGE=usage{Pn}, ACTUAL={Pn},
ACCEPT=list/range],$
```

where:

**MAPVALUE**
Indicates that the segment depends on a MAPFIELD in its parent segment.

**alias**
Is the primary MAPFIELD value that identifies the segment. If there is an ACCEPT list, this value is any value in the ACCEPT list or range.

**usage**
Is the same format as the MAPFIELD format in the parent segment.

**actual**
Is the same format as the MAPFIELD format in the parent segment.

**list**
Is a list of one or more lines of specific MAPFIELD values for records that have the same segment layout. The maximum number of characters allowed in the list is 255. Each item in the list must be separated by either a blank or the keyword OR. If an item in the list contains embedded blanks or commas, it must be enclosed within single quotation marks ('). The list may contain a single MAPFIELD value. For example:

```
FIELDNAME=MAPVALUE, ALIAS=A, USAGE=A1, ACTUAL=A1, ACCEPT=A OR B OR C,$
```

**range**
Is a range of one or more lines of MAPFIELD values for records that have the same segment layout. The maximum number of characters allowed in the range is 255. If either value in the range contains embedded blanks or commas, it must be enclosed in single quotation marks (').

To specify a range of values, include the lowest value, the keyword TO, and the highest value, in that order.

In some cases, the record type indicates what kind of repeating data will follow. Schematically, the records would look like the following:

```
A  B  Recordtype (1)  C  D  C  D  C  D
A  B  Recordtype (2)  E  E
```

The first record contains "header" information, values for A and B, followed by an OCCURS segment of C and D that was identified by its preceding record type indicator. The second record has a different record type indicator and contains a different repeating group, this time for E.
Since the OCCURS segments are identified by the record type indicator, rather than the parent A/B segment, you can use the keyword MAPFIELD. MAPFIELD identifies a field like RECTYPE, but, since the OCCURS segments will each have specific values for MAPFIELD, its value is associated with each OCCURS segment by means of a complementary field named MAPVALUE.

The Master File for this file would look like the following:

FILENAME=EXAMPLE,SUFFIX=RMS,$
GROUP=ONE           ,ALIAS=KEY       ,ACTUAL=A2     ,USAGE=A2  ,$
FIELDNAME=A        ,ALIAS=          ,USAGE=A2     ,ACTUAL=A2 ,$
FIELDNAME=B        ,ALIAS=          ,USAGE=A10    ,ACTUAL=A10 ,$
FIELDNAME=FLAG     ,ALIAS= MAPFIELD ,USAGE=A1     ,ACTUAL=A1 ,$
SEGNAME=TWO,SEGTYPE=S0,PARENT=ONE,OCURS=VARIABLE, $
FIELDNAME=C        ,ALIAS=          ,USAGE=A5     ,ACTUAL=A5 ,$
FIELDNAME=D        ,ALIAS=          ,USAGE=A7     ,ACTUAL=A7 ,$
FIELDNAME=MAPVALUE ,ALIAS=1        ,USAGE=A1     ,ACTUAL=A1 ,$
SEGNAME=THREE,SEGTYPE=S0,PARENT=ONE,OCURS=VARIABLE, $
FIELDNAME=E        ,ALIAS=          ,USAGE=D12.2  ,ACTUAL=D8 ,$
FIELDNAME=MAPVALUE ,ALIAS=2        ,USAGE=A1     ,ACTUAL=A1 ,$

**Associating an RMS Data Source to a Master File**

**In this section:**

When to Use an Access File With an RMS Data Source

File and Record Locking

File Locking and the Interface to RMS

Record Locking

Handling Locked Records During Table Read Request

**How to:**

Specify a Physical File Location for the RMS Data Source

Associate an RMS Data Source in an Access File

**Example:**

Allocating an RMS Data Source Using the DATASET Attribute

Overriding DATASET and RMSFILE With a FILEDEF Command

You can associate an RMS file to a Master File using the following methods:
- **DATASET attribute in a Master File.** The DATASET attribute in a Master File specifies the physical location for the data source to be allocated. This attribute is used at the file declaration level of the Master File. The synonym creation facility uses the DATASET attribute in the Master File. For details, see *How to Specify a Physical File Location for the RMS Data Source* on page 2024.

- **RMSFILE attribute in an Access File.** You can use either the RMSFILE attribute or a DATESET attribute if you are creating Master and Access Files from scratch using a text editor. For details, see *How to Associate an RMS Data Source in an Access File* on page 2025.

- **FILEDEF command.** An explicit allocation (FILEDEF) of data for the Master File is checked for when a DATASET or RMSFILE attribute is detected. If an explicit allocation is found, the DATASET and RMSFILE attributes are ignored and the allocation is used.

  If the data file name is not allocated, an internal command is issued to perform the allocation using the DATASET or RMSFILE values. This allocation is stored temporarily and is released when a new Master File is used or when the session terminates.

  If both attributes exist, DATASET takes precedence over RMSFILE. However, an explicit FILEDEF command takes precedence over both the DATASET and RMSFILE attributes.

**Syntax:**  
*How to Specify a Physical File Location for the RMS Data Source*

The DATASET attribute is used at the file declaration level of the Master File. The syntax is `{DATASET|DATA}='filename`

where:

`filename`

Is the platform-dependent physical name of the data source.

**Note:** If a DATASET allocation is in effect, a CHECK FILE command must be issued in order to override it by an explicit allocation command. The CHECK FILE command will deallocate the allocation created by DATASET.
**Example:** Allocating an RMS Data Source Using the DATASET Attribute

The following example illustrates how to allocate an RMS data source on the file declaration level and for an alternate index:

```plaintext
FILE=EXERVSM1, SUFFIX=RMS,$
DATASET='MYDISK:[mydata.sample]testdata.dat',$
SEGNAME=ROOT , SEGTYPE=S0,$
GROUP=KEY1  , ALIAS=KEY , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD1 , ALIAS=F1  , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD2 , ALIAS=F2  , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD3 , ALIAS=DD1 , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD4 , ALIAS=F4  , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD5 , ALIAS=F5  , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD6 , ALIAS=F6  , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD7 , ALIAS=F7  , FORMAT=A4, ACTUAL=A4 ,$
```

**Syntax:** How to Associate an RMS Data Source in an Access File

The Access File has the following format

```plaintext
RMSFILE   = filename, 
[ACCESS   = {SHARED|READONLY},]
[LOCKMODE = {SKIP|KEEP },]
[STATMODE = {EXCEPTIONS|ON|OFF},] $ 
```

where:

`filename`

- Is one of the following:
  - A fully qualified file name, including files on remote hosts.
  - A logical that points to a local or fully qualified RMS file.

**Example:** Overriding DATASET and RMSFILE With a FILEDEF Command

You can override the DATASET value in the Master File or the RMSFILE declaration in the Access File with a FILEDEF command. The FILEDEF can be done locally within a procedure (before accessing the file) or within the profile. For example,

```plaintext
FILEDEF rmsfile DISK filename
```

where:

`rmsfile`

- Is the logical metadata reference name matching the physical file name.
filename

Is the OpenVMS file name. It may be any valid OpenVMS file specification or logical name pointing to a file.

When to Use an Access File With an RMS Data Source

An Access File is optional for an RMS data source if the DATASET attribute is used in the Master File and if WRITE access is not required. However, even in those instances, you may wish to have an Access File to specify ACCESS, LOCKMODE, and STATMODE for RMS files:

- ACCESS attribute can have a value of SHARED for read/write access, or READONLY for Read access. READONLY is the default setting.

- LOCKMODE attribute is for retrieval only, and can have a value of SKIP or KEEP. If you select SKIP, the Adapter for RMS skips locked records. If you select KEEP, the Adapter for RMS retrieves locked records.

- STATMODE attribute can have a value of EXCEPTIONS, ON, or OFF. EXCEPTIONS is the default and displays a message when locked records are encountered. ON allows a message to occur (whether or not locked records are encountered), and OFF suppresses locking messages.

See File and Record Locking on page 2026 for more information on ACCESS, LOCKMODE, and STATMODE. For related information, see Handling Locked Records During Table Read Request on page 2028.

File and Record Locking

This topic describes features that enable a developer to control file and record locking. Lock conflict, or contention, can occur at file level or record level. File contention is caused by incompatible access by two or more processes. Record contention is caused when a requested lock is incompatible with any existing locks on the record.

The following terms summarize the types of access allowed to RMS files and records:

<table>
<thead>
<tr>
<th>Access Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Read Access</strong></td>
<td>Provides users with access to a file and the records in the file for actions that make no alterations. Read can use any access mode (dependent on site needs) for the actions that are defined in the following tables.</td>
</tr>
<tr>
<td><strong>Read/Write Access</strong></td>
<td>Provides users with access to a file and the records in the file for actions that make alterations to records, add records, or delete records. Read/write access requires the use of SHARED as the access mode. All other modes are not supported WRITE operations.</td>
</tr>
</tbody>
</table>
File Locking and the Interface to RMS

When your request attempts to open an RMS file, the Access Parameter within the Access File determines what you can do at a file level with the RMS file, and what actions others can take while you have the file open.

When a request attempts to open an RMS file, the Access Parameter determines which type of access to use. If the Access Parameter specification is incompatible with another process' access to the file, the procedure fails because it is not able to open the file. Additionally, if the file is opened for read, but a subsequent write is attempted, it will fail due to an inappropriate access mode.

Depending on how a file is opened, as specified by the Access Parameter, subsequent opens are limited as follows:

<table>
<thead>
<tr>
<th>Processes by Server Users</th>
<th>Processes by Others</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>READONLY</td>
</tr>
<tr>
<td>READONLY</td>
<td>Allowed</td>
</tr>
<tr>
<td>SHARED</td>
<td>Allowed</td>
</tr>
</tbody>
</table>

This table describes user access and file sharing options used in response to the following Access File options for the Access Parameter.

<table>
<thead>
<tr>
<th>Access Parameter</th>
<th>User Access</th>
<th>File Sharing to Other Processes</th>
</tr>
</thead>
<tbody>
<tr>
<td>READONLY</td>
<td>Read</td>
<td>Read and Write</td>
</tr>
<tr>
<td>SHARED</td>
<td>Read and Write</td>
<td>Read and Write</td>
</tr>
</tbody>
</table>

Record Locking

RMS requests are no-lock for each record retrieved for READ operations.
Handling Locked Records During Table Read Request

RMS files can be accessed while they are simultaneously accessed by other programs. For instance, the file might be in use by another program that is maintaining it by adding, deleting, or updating records.

When a READ operation is rejected due to a lock conflict by another process, the request is aborted and the following message is displayed:

(FOC1325) RMS READ LOCK ABORT ERROR

You can override this behavior on a file-by-file basis using the LOCKMODE and STATMODE options in the Access File. LOCKMODE and STATMODE do not apply to WRITE requests such as UPDATE or DELETE.

**LOCKMODE**

LOCKMODE can affect record retrieval in one of two ways. Each of these settings and the affect they have on the retrieval process is as follows:

- **Omitting LOCKMODE from the acx file.**
  
  To halt retrieval when locked records are encountered, omit LOCKMODE from the acx file. A (FOC1325) RMS READ LOCK ABORT ERROR will be sent if locked records are encountered during record retrieval. Records retrieved before the lock is encountered may have already been sent to the client and should be discarded.

- **Setting one of two acceptable values in the acx file.**

- **To retrieve all records, including locked records, code LOCKMODE=KEEP in the acx file.**
  
  For example:

  LOCKMODE = KEEP

- **To retrieve all records, except locked records, and complete the request, code LOCKMODE=SKIP in the acx file.**
  
  For example:

  LOCKMODE = SKIP
STATMODE

Example:
Sample Uses for an Access File

STATMODE controls whether or not a message is sent to the client program about retrieved records. STATMODE has three settings:

- **ON**
  
  To receive a message giving the statistics of data retrieval, set STATMODE to ON in the Access File. The message displays, in addition to the report request, after data retrieval is complete. For example:

  ```
  STATMODE = ON
  ```

  A FOC1320 message displays when no locked records are encountered. For example:

  ```
  (FOC1320) RMS STATS : (SEGCAR ) Reads = 1, Skips = 0, Keeps = 0
  ```

  If LOCKMODE is set to KEEP, a FOC1324 message displays. For example:

  ```
  (FOC1324) RMS KEEP : (SEGCAR ) Reads = 1, Skips = 2, Keeps = 0
  ```

  If LOCKMODE is set to SKIP, a FOC1322 message displays. For example:

  ```
  (FOC1322) RMS SKIP : (SEGCAR ) Reads = 1, Skips = 0, Keeps = 2
  ```

- **OFF**

  Set the STATMODE to OFF if no messages are to be sent when locked records are encountered. The client application will not have any indication whether or not locked records were encountered during record retrieval.

- **EXCEPTIONS**

  To receive a message giving the statistics of data retrieval, only if locked records are encountered, set the STATMODE to EXCEPTIONS. The message displays, in addition to the report request, after data retrieval is complete. No message displays if no locked records are encountered during retrieval. For example:

  ```
  STATMODE = EXCEPTIONS
  ```

  If LOCKMODE is set to KEEP, a FOC1324 message displays. For example:

  ```
  (FOC1324) RMS KEEP : (SEGCAR ) Reads = 1, Skips = 2, Keeps = 0
  ```

  If LOCKMODE is set to SKIP, in addition to the report output, a FOC1322 message displays. For example:

  ```
  (FOC1322) RMS SKIP : (SEGCAR ) Reads = 1, Skips = 0, Keeps = 2
  ```
**Example:**  **Sample Uses for an Access File**

The following is an example of a Remote Node:

```
RMSFILE=HOST1::DISK$PROG:\[PROD.INFO\]EMPINFO.DAT,ACCESS=SHARED,$
```

The following is an example of a Full Path as defined by a logical and a file name:

```
RMSFILE=DATADIR:PERSON.DAT,ACCESS=READONLY,$
```

The following is an example of a Logical Name:

```
RMSFILE=MYLOGICAL,ACCESS=SHARED,$
```

The following is an example of a Full Path on a file using LOCKMODE and STATMODE:

```
RMSFILE=DISK100:[DATA]PERSON.DAT,ACCESS=READONLY,LOCKMODE=SKIP,
STATMODE=OFF,$
```

**Retrieving Data From RMS Files**

**In this section:**
- Index Selection
- Automatic Index Selection (AIS)
- Requirements for Using AIS

The following topics outline the procedures necessary for retrieving data from RMS files.

**Index Selection**

By default, the primary key is used for retrieval of records from indexed RMS files. You can override this default with the Automatic Index Selection (AIS).

The primary benefit of keys is improved efficiency in record retrieval. They provide an alternate, more efficient, retrieval method and can be used with screening tests on the selected key which are translated into direct reads. Indexes can also be used to control the order of retrieval of records.

To screen more than one field when working with group keys that are comprised of multiple fields, use a slash (/) character to separate the components of the group key. Screening is limited to NE, IS, and EQ relationships. The syntax is

```
... groupname {NE|IS|EQ]['value/value.../value'}
```

where:

- **groupname**
  
  Is the GROUP field name in the Master File.
The slash (/) separates the parts of the group field. If you omit the optional quotation marks, embedded blanks in the value will be removed. Use single quotations marks (') around the values to preserve the values exactly as typed.

**Automatic Index Selection (AIS)**

The Automatic Index Selection (AIS) facility automatically selects a key for direct access to an indexed file based on a request.

**Requirements for Using AIS**

AIS automatically uses a key for direct retrieval when an applicable screening condition is reached in a request. AIS is used when all of the following requirements are met:

- Primary keys are described in a Master File with the ALIAS=KEY or ALIAS=DKEY attribute placed on the GROUP declaration (not on every field in the GROUP). Note that the primary key must always be described as a GROUP.
- Secondary keys are described with the FIELDTYPE attribute on the GROUP or on the FIELD declaration for a secondary key not belonging to a group.
- There is an optimizable screening condition on a key field. If a key is defined as a GROUP, the screening condition must be on either the GROUP name, or on the first field of the key. Only those key fields in a screening condition with one of the following logical relations are used for index selection:
  - Equal
  - Less than or equal to
  - Less than
  - Greater than
  - Greater than or equal to
- AIS applies only to keys in the root segment.
**Syntax for RMS Master File Attributes**

This topic details the syntax for the attributes used to describe files, segments, and fields.

**File Attributes**

File Declaration:

```
FILE[NAME]=filename, SUFFIX=type, {DATASET|DATA}='filename',$
```

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Function</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE[NAME]</td>
<td>Identifies the Master File.</td>
<td>All characters and digits, but no embedded blanks. Eight characters maximum.</td>
</tr>
<tr>
<td>SUFFIX</td>
<td>Identifies the type of file to which the Master File applies.</td>
<td>RMS.</td>
</tr>
<tr>
<td>DATASET</td>
<td>DATA</td>
<td>Identifies the physical location of the data source. Optional attribute. The RMSFILE attribute in the Access File or a FILEDEF command are alternatives. For more information, see <em>Associating an RMS Data Source to a Master File</em> on page 2023.</td>
</tr>
</tbody>
</table>

**Note:** The SUFFIX values listed here pertain to the RMS files. The SUFFIX parameter can have other values for data that resides on other Database Management Systems that can be accessed. Consult the appropriate Adapter manuals for these products.
Except for the following differences, the description of data and relationships between fields within a file is the same for keyed (indexed) and non-keyed RMS files, FIX (fixed-format sequential) files, and COM (comma-delimited) files. Keyed and non-keyed RMS file use RMS File System API calls to access data. The others use sequential file reads for accessing the data source. Index-related declarations do not apply to fixed-sequential or comma-delimited files.

**Segment Attributes**

Segment Declaration:

\[ \text{SEGMENT}=\text{segname}[,\text{SEGTYPE}=\text{S0}][,\text{PARENT}=\text{parent\_name}] \\
\quad[\{n\}] \\
\quad[,\text{OCCURS}=\{\text{fieldname}\}] \\
\quad[,\text{POSITION}=\text{fieldname}],$, \\
\quad[\{\text{VARIABLE}\}] \]

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Function</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SEGNAME</strong></td>
<td>Identifies a collection of data fields that are related.</td>
<td>All characters and digits, except special characters. Up to eight characters in length.</td>
</tr>
<tr>
<td><strong>SEGMENT</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>SEGTYPE</strong></td>
<td>Identifies the physical storage of the segment.</td>
<td>S0.</td>
</tr>
<tr>
<td><strong>PARENT</strong></td>
<td>Identifies the &quot;parent&quot; or owner of the current segment.</td>
<td>Any valid segment name previously defined in the Master File.</td>
</tr>
<tr>
<td><strong>OCCURS</strong></td>
<td>Identifies the field as a multiply-occurring field and specifies how the number of occurrences will be determined.</td>
<td>Any integer from 1 to 4095 or any valid field name or VARIABLE.</td>
</tr>
<tr>
<td><strong>POSITION</strong></td>
<td>Identifies the field in the parent that marks the beginning of the multiply-occurring fields.</td>
<td>All characters and digits, except special characters.</td>
</tr>
</tbody>
</table>
## Field Attributes

Field Declarations:

```lang
{fieldname}        {alias        }
FIELD[NAME]= {FILLER   } ALIAS= {rectype identifier},USAGE=usage,  
(RECTYPE    }        (ORDER       )  
{MAPVALUE    }        (KEY(n)       )  
(MAPFIELD    }                     

ACTUAL=actual [,FIELDTYPE =I,ACCEPT{list  }]}  
[ ,INDEX=I      {range}]  
[ ,TITLE='text'][,DESCRIPTION]=description],$  
GROUP= {groupname|keyname} ,ALIAS={DKEY(n)|KEY(n)}  
,USAGE=usage,ACTUAL=actual [,FIELDTYPE=I],$  

[DEFINE name/format=expression;$]
```

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Function</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIELDNAME</td>
<td>Uniquely identifies a data item in the file.</td>
<td>All characters and digits, with a maximum of 64.</td>
</tr>
<tr>
<td>ALIAS</td>
<td>Alternate field name, sometimes used to provide additional information about the field.</td>
<td>All characters and digits, except special characters, with a maximum of 64.</td>
</tr>
<tr>
<td>USAGE</td>
<td>Describes the format of the field as interpreted for usage (display) purposes.</td>
<td>See RMS Attribute Summary on page 2035.</td>
</tr>
<tr>
<td>ACCEPT</td>
<td>Assigns a list or range of acceptable values for RECTYPE or MAPVALUE.</td>
<td>See RMS Attribute Summary on page 2035.</td>
</tr>
<tr>
<td>ACTUAL</td>
<td>Describes the format of the field as it exists in the external file.</td>
<td>See RMS Attribute Summary on page 2035.</td>
</tr>
<tr>
<td>FIELDTYPE</td>
<td>Identifies a group field on keyfield.</td>
<td>Can be only one character, which is I.</td>
</tr>
<tr>
<td>TITLE</td>
<td>Provides one or more lines of text to be used as an alternate column heading for the field name on reports.</td>
<td>All characters and digits with a maximum of 64.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Function</td>
<td>Value</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>Documents the meaning of a field in the Master File.</td>
<td>All characters and digits, with a maximum of 44.</td>
</tr>
<tr>
<td>GROUP</td>
<td>Identifies a key.</td>
<td>All characters and digits, except special characters, with a maximum of 48.</td>
</tr>
<tr>
<td>DEFINE</td>
<td>Creates a temporary field for reporting purposes.</td>
<td>Mathematical or logical statement made up of constants, field names, or other DEFINE fields.</td>
</tr>
</tbody>
</table>

**RMS Attribute Summary**

This topic contains a summary of the attributes.

Throughout the summary we refer to special characters and denote this reference with an "**". You should avoid using the special characters listed below, as they may impose operational restrictions in some environments.

<table>
<thead>
<tr>
<th>+ (plus sign)</th>
<th>' (apostrophe)</th>
<th>: (double quotation marks)</th>
</tr>
</thead>
<tbody>
<tr>
<td>- (hyphen)</td>
<td>; (semicolon)</td>
<td>&lt; (less than sign)</td>
</tr>
<tr>
<td>$ (dollar sign)</td>
<td>, (comma)</td>
<td>&gt; (greater than sign)</td>
</tr>
<tr>
<td>* (asterisk)</td>
<td></td>
<td>= (equal sign)</td>
</tr>
<tr>
<td>/ (slash)</td>
<td></td>
<td>. (period)</td>
</tr>
<tr>
<td>() (parentheses)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Attribute</td>
<td>ACCEPT</td>
<td></td>
</tr>
<tr>
<td>-----------</td>
<td>--------</td>
<td></td>
</tr>
<tr>
<td><strong>Length:</strong></td>
<td>1 to 255 characters</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>ACCEPT = A OR B OR C</td>
<td></td>
</tr>
<tr>
<td><strong>Function:</strong></td>
<td>Is optional, and enables you to assign a list or range of acceptable values to a RECTYPE or MAPVALUE field in a file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The syntax is</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ACCEPT = {list</td>
<td>range}</td>
</tr>
<tr>
<td></td>
<td>where:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>list</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Is a string of acceptable values:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>value1 OR value2 OR value3...</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For example, ACCEPT=RED OR WHITE OR BLUE. You can also use a blank as an item separator. If the list of acceptable values runs longer than one line, continue it on the next line. The list is terminated by a comma (,).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>range</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Gives the range of acceptable values:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>value1 TO value2</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ACCEPT = 150 TO 1000</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attribute</th>
<th>ACTUAL</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Length:</strong></td>
<td>1 to 8 characters.</td>
</tr>
</tbody>
</table>
### Attribute: ACTUAL

#### Function:
Describes the type and length of a field as it actually exists in a file. The source of this information is an existing description of the file. The following chart shows the data format types that the server reads:

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>An</td>
<td>Alphanumeric characters A&quot;Z, 0&quot;9, and other ASCII display characters, where ( n = 1^\text{256} ).</td>
</tr>
<tr>
<td>D8</td>
<td>8-byte double-precision floating-point numbers.</td>
</tr>
<tr>
<td>F4</td>
<td>4-byte single-precision floating-point numbers.</td>
</tr>
</tbody>
</table>
| In   | Binary integers:  
| I1   | Single-byte binary integer  
| I2   | 2-byte binary integer  
| I4   | 4-byte binary integer  
| I8   | 8-byte binary integer |
| Pn   | Packed decimal internal format. The length is the number of bytes, each of which contains two digits, except for the last byte which contains a digit and the sign (+ or -). P6 means 11 digits plus a sign, packed 2 digits to the byte, for a total of 6 bytes of storage, where \( n = 1^8 \). |
Zoned decimal format (numeric string) where \( n \) is the number of digits (1 to 31), each of which takes one byte of storage. The last byte contains a digit and the sign.

There are several standards for zoned data. For Read purposes, only right overpunched standards are supported and can be determined on Read since they are unique.

The specific format to use when writing data must be known for read/write purposes. The default is ASCII right overpunch. To change the default, you must edit the EDACONF [.BIN]EDAENV.COM file and add the following logical:

```
DEFINE /NOLOG IBI_ZONED_OUT_TYPE {1 | 2}
```

where:

1. Is the ASCII right overpunched standard (default).
2. Is the EBCDIC right overpunched standard.

Zoned right separate numeric or zoned left overpunched numeric formats are not supported.

Unless your file was created by a program, all of the characters will be in ASCII format type A (alphanumeric).

The server permits the following conversions from ACTUAL format to USAGE (display) format:

<table>
<thead>
<tr>
<th>USAGE</th>
<th>ACTUAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>I</td>
</tr>
<tr>
<td>P</td>
<td>P</td>
</tr>
<tr>
<td>P,D,I,F</td>
<td>Z</td>
</tr>
<tr>
<td>D</td>
<td>D</td>
</tr>
<tr>
<td>F</td>
<td>F</td>
</tr>
<tr>
<td>P</td>
<td>I8</td>
</tr>
<tr>
<td>YYMD</td>
<td>DATE</td>
</tr>
</tbody>
</table>
For a complete list of date formats, see Segment Attributes on page 1993.

Note: The ACTUAL value of DATE indicates that the field is an OpenVMS 64-bit datetime stamp. This usage also requires an A4 filler field immediately following the date field in the Master File.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>ALIAS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alias:</td>
<td>SYNONYM</td>
</tr>
<tr>
<td>Length:</td>
<td>1 to 12 characters</td>
</tr>
<tr>
<td>Permitted Values:</td>
<td>All characters and digits.</td>
</tr>
<tr>
<td>Example:</td>
<td>ALIAS=CTY</td>
</tr>
<tr>
<td>Function:</td>
<td>Is an alternate name to identify a data field. Since references to data fields are based on the names, aliases, or shortest unique truncation, it is useful to make the ALIAS a short abbreviation representative of the data. Short, simple names are best, with no embedded blank spaces or special characters. For example, PART CODE or PART-CODE should be PARTCODE or PART_CODE, or PC. Names must begin with a letter, but can contain numbers. Do not use names that might conflict with report column names (C1, C2, ...), row names (R1, R2, ...) or HOLD file aliases (E01, E02, ...). Also, avoid reserved keywords such as BY or ACROSS. ALIAS has specialized functions when used with KEY definitions, RECTYPE and MAPFIELD, as discussed at the beginning of this manual.</td>
</tr>
<tr>
<td>Attribute:</td>
<td>DEFINE</td>
</tr>
<tr>
<td>-----------</td>
<td>--------</td>
</tr>
<tr>
<td>Example:</td>
<td>DEFINE PROFIT/D8 = RETAIL_COST - DEALER_COST;$</td>
</tr>
</tbody>
</table>
| Function: | Is optional, and enables you to store definitions for temporary fields in your Master File for reporting purposes. The syntax is DEFINE name[/format] = expression;$ where:  
  
  name  
  Is a 1 to 48 character field name for the defined field.  
  
  format  
  Is the optional display format for the defined field, separated from name by a slash (/). The display format for the field follows the rules for USAGE formats described under field attributes. The default value is D12.2.  
  
  expression  
  Can be either a mathematical or logical statement, made up of constants, database fields, and temporary defined fields. The expression must end with a semicolon (;) followed by a dollar sign ($). A DEFINE is placed at the end of the segment it is associated with.  
  
  A defined field stored in a Master File can refer only to fields in its same segment. To create a defined field that refers to fields in other segments, create a temporary field using the DEFINE command prior to your report request. |
<table>
<thead>
<tr>
<th>Attribute:</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length:</td>
<td>1 to 44 characters</td>
</tr>
<tr>
<td>Permitted Values:</td>
<td>All characters and digits.</td>
</tr>
<tr>
<td>Example:</td>
<td>DESCRIPTION=STANDARD COST CATEGORY,$</td>
</tr>
</tbody>
</table>

**Function:**

Is optional, and is used only for documenting the meaning of a field in the Master File. It is ignored during processing. Since a Master File is a comma-delimited file that the server can read directly, it is possible to prepare reports in various formats whose subjects are the names and attributes of the data fields.

If the DESCRIPTION contains a comma (,), the entire text must be enclosed in single quotation marks ('). For example:

```
DESCRIPTION='TOTAL COST, NOT NORMALIZED',$
```

Another way to add comments to a Master File is to place them after the dollar sign ($).

Descriptions of DEFINE fields in the Master File are placed on separate lines.

For example:

```
DEFINE ITEMS_SOLD/D8 = INVENTORY - ORDERED ; DESC=DAMAGED ITEMS NOT INCLUDED,$
```

**Note:** When used on a DEFINE expression, the dollar sign ($) does not immediately follow the semicolon (;).

The semicolon (;) after a DEFINE must display on the same line as the attribute, which follows the DEFINE.
### FIELDNAME

<table>
<thead>
<tr>
<th>Attribute:</th>
<th>FIELDNAME</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Alias:</strong></td>
<td>FIELD</td>
</tr>
<tr>
<td><strong>Length:</strong></td>
<td>1 to 64 characters</td>
</tr>
<tr>
<td><strong>Permitted Values:</strong></td>
<td>All characters and digits.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>FIELD=INVENTORY</td>
</tr>
<tr>
<td><strong>Function:</strong></td>
<td>Identifies the data items in a file. Names must be unique within a file. The full field name is used as the default title for the data printed on reports. Hence, names representative of the data should be selected. Names must begin with a letter, though they may contain numbers. Avoid names that might conflict with report column names (C1, C2, ...), row names (R1, R2, ...) or HOLD file aliases (E01, E02, ...). Also avoid reserved keywords such as PRINT, BY, ACROSS, and so on. FIELDNAME has specialized functions when used with RECTYPE and MAPVALUE, as discussed at the beginning of this manual.</td>
</tr>
</tbody>
</table>

### FIELDDTYPE

<table>
<thead>
<tr>
<th>Attribute:</th>
<th>FIELDDTYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Alias:</strong></td>
<td>INDEX</td>
</tr>
<tr>
<td><strong>Length:</strong></td>
<td>1 character</td>
</tr>
<tr>
<td><strong>Permitted Values:</strong></td>
<td>I</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>FIELDDTYPE=I</td>
</tr>
<tr>
<td><strong>Function:</strong></td>
<td>Identifies a group field or a field that serves as a secondary key, which indicates that this secondary key can be used for direct retrieval. This attribute only applies to keyed (indexed) RMS files.</td>
</tr>
</tbody>
</table>
### Attribute: FILENAME

**Alias:** FILE  

**Length:** 1 to 8 characters  

**Permitted Values:** All characters and digits, but no embedded blanks.  

**Example:** `FILENAME=EQUIP`  

**Function:** Is optional, and is used for documentation purposes. It should correspond to the external file name of the Master File.

### Attribute: GROUP

**Alias:** KEY  

**Length:** 1 to 66 characters  

**Permitted Values:** All characters and digits, but no embedded blanks.  

**Example:** `GROUP=PUBKEY`  

**Function:** Is used to describe the primary key in a keyed file or a field that is composed of subfields. The USAGE format and ACTUAL format of the GROUP is calculated using the USAGE and ACTUAL formats of the FIELDS that comprise the GROUP.  

Names must begin with a letter, though they may contain numbers. Avoid using names that might conflict with report column names (C1, C2, ...), row names (R1, R2, ...), or HOLD file aliases (E01, E02, ...).
<table>
<thead>
<tr>
<th>Attribute:</th>
<th>PARENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alias:</td>
<td>PARENT</td>
</tr>
<tr>
<td>Length:</td>
<td>1 to 8 characters</td>
</tr>
<tr>
<td>Permitted Values:</td>
<td>All characters and digits, but no embedded blanks.</td>
</tr>
<tr>
<td>Example:</td>
<td>PARENT=CARSEG</td>
</tr>
<tr>
<td>Function:</td>
<td>Is the name of the segment that is the parent or &quot;owner&quot; of the current segment. In the Master File, the information describing the parent must precede any reference to it as a parent. The first, or &quot;root&quot; segment, in a file cannot have a parent by definition, but the name &quot;SYSTEM&quot; may be used, or the attribute left blank. Every other segment must have a parent named. If no parent is named, the immediately preceding segment will be used by default.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attribute:</th>
<th>SEGNAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alias:</td>
<td>SEGMENT</td>
</tr>
<tr>
<td>Length:</td>
<td>1 to 8 characters</td>
</tr>
<tr>
<td>Permitted Values:</td>
<td>All characters and digits, but no embedded blanks.</td>
</tr>
<tr>
<td>Example:</td>
<td>SEGNAME=MODSEG</td>
</tr>
<tr>
<td>Function:</td>
<td>Identifies a collection of data fields. Segments which have a relationship to each other must have unique names within a given file description.</td>
</tr>
</tbody>
</table>
### Attribute: SUFFIX

<table>
<thead>
<tr>
<th>Alias:</th>
<th>FILESUFFIX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length:</td>
<td>1 to 8 characters</td>
</tr>
<tr>
<td>Permitted Values:</td>
<td>RMS</td>
</tr>
<tr>
<td>Example:</td>
<td>SUFFIX=RMS</td>
</tr>
</tbody>
</table>

**Function:** In order to identify the type of file the description applies to, the SUFFIX is given one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMS</td>
<td>A keyed RMS file, which uses an Access File to locate and access data using the RMS Index.</td>
</tr>
<tr>
<td>ISAM</td>
<td>A keyed RMS file. ISAM is supported as an alternate keyword for backward compatibility to FOCUS 6.x applications.</td>
</tr>
</tbody>
</table>

**Note:** SUFFIX values for other proprietary databases that can be accessed are described in the appropriate manuals for these options.
### Attribute: TITLE

<table>
<thead>
<tr>
<th><strong>Length:</strong></th>
<th>1 to 64 characters.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Permitted Values:</strong></td>
<td>All characters and values.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>TITLE='Products'</td>
</tr>
<tr>
<td><strong>Function:</strong></td>
<td>Is optional, and enables you to supply an alternate column title to replace the field name that is normally used. The syntax is TITLE='text' where: text Must be enclosed within single quotation marks ('') and can contain 1 to 64 characters. TITLE cannot span more than one line in the Master File. If necessary, move the entire attribute to a line by itself. To display the TITLE on more than one line in the report, use commas to divide the text. To include blanks at the end of a column title, simply type them in and enter a slash (/) in the final blank position. TITLE attributes do not apply when direct operations (PCT., AVE., ...) are used on the field. To rename such columns, use the AS phrase.</td>
</tr>
<tr>
<td><strong>Changes:</strong></td>
<td>You can override both field names and TITLE attributes with AS phrases in your request. You can issue a SET TITLE command to change the default titles to either the field names or titles supplied in the Master File. You can change the TITLE attribute in the Master File.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>Client tools using the API do not have access to the TITLE attribute. The TITLE attribute is available only with WebFOCUS.</td>
</tr>
</tbody>
</table>
**Attribute:** USAGE

**Length:** 1 to 8 characters

**Function:** Defines the report display format of the data field. This attribute defines the data field type, length, and any edit options that are to be applied when the field values are printed. Special date formats, which are actually an extended series of edit options, can also be used.

The syntax is

```
USAGE=usage
```

where:

- **usage**
  - Consists of three parts: `tllleeeeee`
  - **t** = field type
  - **l** = field display length
  - **e** = edit options

Permissible USAGE field types and lengths are shown in the chart below:

<table>
<thead>
<tr>
<th>USAGE</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1-9,095</td>
<td>Alphanumeric text</td>
</tr>
<tr>
<td>D</td>
<td>1-19</td>
<td>Decimal, double-precision numbers</td>
</tr>
<tr>
<td>F</td>
<td>1-9</td>
<td>Decimal, single-precision numbers</td>
</tr>
<tr>
<td>I</td>
<td>1-11</td>
<td>Integer values (no decimal places)</td>
</tr>
<tr>
<td>P</td>
<td>1-17</td>
<td>Packed decimal numbers</td>
</tr>
<tr>
<td>YYMD</td>
<td>10</td>
<td>Displayed as YYMD</td>
</tr>
</tbody>
</table>

Edit options only affect printed or displayed fields. They are not active for extract files.
The following table summarizes the edit options and includes sample USAGE values:

<table>
<thead>
<tr>
<th><strong>Edit Option</strong></th>
<th><strong>Meaning</strong></th>
<th><strong>Effect</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>Percent sign</td>
<td>Displays a percent sign along with numeric data. Does not calculate the percent.</td>
</tr>
<tr>
<td>B</td>
<td>Bracket negative</td>
<td>Encloses negative numbers in parentheses.</td>
</tr>
<tr>
<td>C</td>
<td>Comma suppress</td>
<td>Suppresses the display of commas. Used with numeric format options M and N (floating and non-floating dollar sign) and data format D (floating-point double-precision).</td>
</tr>
<tr>
<td>C</td>
<td>Comma edit</td>
<td>Inserts a comma after every third significant digit, or a period instead of a comma if continental decimal notation is in use.</td>
</tr>
<tr>
<td>DMY</td>
<td>Day-Month-Year</td>
<td>Displays alphanumeric or integer data as a date in the form day/month/year.</td>
</tr>
<tr>
<td>E</td>
<td>Scientific notation</td>
<td>Scientific notation Displays only significant digits.</td>
</tr>
<tr>
<td>L</td>
<td>Leading zeroes</td>
<td>Adds leading zeroes.</td>
</tr>
<tr>
<td>M</td>
<td>Floating $ (for US code page)</td>
<td>Places a floating dollar sign $ to the left of the highest significant digit. <strong>Note:</strong> The currency symbol displayed depends on the code page used.</td>
</tr>
<tr>
<td>MDY</td>
<td>Month-Day-Year</td>
<td>Displays alphanumeric or integer data as a date in the form month/day/year.</td>
</tr>
<tr>
<td>N</td>
<td>Fixed $(for US code page)</td>
<td>Places a dollar sign $ to the left of the field. The symbol displays only on the first detail line of each page. <strong>Note:</strong> The currency symbol displayed depends on the code page used.</td>
</tr>
<tr>
<td>R</td>
<td>Credit (CR) negative</td>
<td>Places CR after negative numbers.</td>
</tr>
<tr>
<td>S</td>
<td>Zero suppress</td>
<td>Zero suppress If the data value is zero, prints a blank in its place.</td>
</tr>
</tbody>
</table>
Read/Write Usage Limitations of the Adapter for RMS

In this section:
- OCCURS Statements in a Master File
- Commit Processing
- SQL Commands
- SQL, MODIFY and MAINTAIN Operations

The adapter has certain limitations when used for write purposes. The following topics discuss these issues and possible alternatives that may be used.

OCCURS Statements in a Master File

OCCURS statements in a Master File are not directly supported by the write portion of the adapter. If an OCCURS statement is for a specific number of instances, an alternate Master File may be coded by using specific naming (for example, AMTDUE OCCURS=12 would be coded as AMTDUE01, AMTDUE02, and so on). The write application must then reference the alternate Master File using the specific fields.

For example:

```plaintext
SEGNAME=MTH, SEGTYPE=S0, PARENT=YEAR, OCCURS=12,$
FIELD=PAYABLES, AP, I8 , I4 , $
```

would be coded as

```plaintext
SEGNAME=MTH, SEGTYPE=S0, PARENT=YEAR, $
FIELD=PAYABLES01, AP01, I8 , I4 , $
FIELD=PAYABLES02, AP02, I8 , I4 , $
FIELD=PAYABLES03, AP03, I8 , I4 , $
FIELD=PAYABLES04, AP04, I8 , I4 , $
FIELD=PAYABLES05, AP05, I8 , I4 , $
FIELD=PAYABLES06, AP06, I8 , I4 , $
FIELD=PAYABLES07, AP07, I8 , I4 , $
FIELD=PAYABLES08, AP08, I8 , I4 , $
FIELD=PAYABLES09, AP09, I8 , I4 , $
FIELD=PAYABLES10, AP10, I8 , I4 , $
FIELD=PAYABLES11, AP11, I8 , I4 , $
FIELD=PAYABLES12, AP12, I8 , I4 , $
```
Commit Processing

The Adapter for RMS, in conjunction with RMS itself, treats a single SQL statement as a complete unit of work. This means that the server automatically commits after every SQL statement. If the front-end application sends an SQL COMMIT or SQL ROLLBACK statement(s), it will be ignored by the adapter.

SQL Commands

The following are acceptable SQL commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT</td>
<td>Retrieves data for the entire table (*) or for specified columns.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Removes one or more records from an RMS keyed file.</td>
</tr>
<tr>
<td>INSERT INTO</td>
<td>Adds data to an RMS keyed file.</td>
</tr>
<tr>
<td>UPDATE</td>

SQL, MODIFY and MAINTAIN Operations

Releases prior to 5.2 of the server did not support multi-record SQL INSERT, DELETE and UPDATE except when done as a PREPARE, plus MODIFY and MAINTAIN were not supported. This limitation is removed as of the 5.2 release. Recoding existing applications that used PREPARE is not required, all methods are supported.
The Adapter for Salesforce.com provides query access to salesforce objects using SOQL, the Salesforce Object Query Language.

**Topics:**
- Configuring the Adapter for Salesforce.com
- Creating Synonyms
Configuring the Adapter for Salesforce.com

**How to:**
Configure the Salesforce.com Adapter
Declare Connection Attributes for Salesforce.com

**Reference:**
Salesforce.com Connection Parameters

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

**Procedure: How to Configure the Salesforce.com Adapter**
You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**
   or
   From the Data Management Console, expand the **Adapters** folder.
   The Adapters folder opens.

2. Expand the **Available** folder, if it is not already expanded.

3. Expand the **ERP** folder, and then expand the **Salesforce** folder.

4. Right-click **Salesforce.com** and select **Configure**.

**Procedure: How to Declare Connection Attributes for Salesforce.com**
You can declare connection attributes for salesforce.com from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**
   or
   From the Data Management Console, expand the **Adapters** folder.
   The Adapters folder opens.

2. Expand the **Available** folder, if it is not already expanded.

3. Expand the **ERP** folder and then expand the **Salesforce.com** folder.

4. Right-click **Salesforce.com** and select **Configure**.
The Add Salesforce.com to Configuration dialog box opens, as shown in the following image.

5. Enter values for the parameters required by the adapter and click Configure.

For a description of these parameters, see Salesforce.com Connection Parameters on page 2053.

Reference: Salesforce.com Connection Parameters

The following list describes the information in the Add Connection to IWAF dialog box. Not all options appear for all applications.

Connection name
Logical name used to identify this particular set of connection attributes. The default is CON01.

User
Salesforce.com user ID (e-mail address).

Password
The password associated with your salesforce.com user ID, followed by the security token. For example, if your password is myPass and your security token is xyyzyx then you would enter myPassxyyzyx.
Salesforce URL

The URL to login to salesforce.com using SOAP. Use the default value provided unless instructed otherwise by customer support.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Creating Synonyms

How to:

Create a Synonym for a Salesforce.com Object
Create a Cluster Join for Salesforce.com Objects
Control the Retrieval of Deleted Records
How to Control the Block Size

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represents the server metadata.

Procedure: How to Create a Synonym for a Salesforce.com Object

1. From the Data Management Console, right-click Application Directories, select New and then Synonym.
   
   The Select adapter to configure or Select connection to create synonym dialog box opens.

2. Select a connection for the configured adapter and click OK.
The first of a series of synonym creation panes opens, showing a list of all of the available salesforce.com objects, as shown in the following image.

3. Select the check box for the objects that you want to create synonyms for.

   If you want to change the name of the synonym from the default name, click the name and edit as needed.

4. Click Create Synonym.

   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:** You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.
**Procedure:** How to Create a Cluster Join for Salesforce.com Objects

A synonym with a cluster join facilitates reporting against multiple salesforce.com objects. Salesforce.com relationships between objects are described in the data models on the web site. Search by data model for a list of the entity relationship diagrams (ERDs) available. For example, the Sales Objects model includes accounts, contacts, opportunities and other related objects. For an example of the Sales Objects model, go to the following Web site:

http://www.salesforce.com/us/developer/docs/api/Content/sforce_api_erd_majors.htm

When you create a cluster join for salesforce.com objects, you must make it a subset of the data model. This allows the join between the objects to be performed by salesforce.com, minimizing the number of queries sent to their servers.

For example, say you wanted to create a synonym that would allow you to report from the contact object to get the first and last name of a contact, and the account object to get the company name. From the model shown in the following image, we can see that there is a relationship *from* Account to Contact.

Here are the steps to create a synonym with a cluster join with that relationship.

1. Right-click an application directory and select *New, Synonym*.
   The Select … connection to create synonym dialog box opens.
2. Select your connection to salesforce.com and click *OK.*
The Select Synonym candidates… dialog box opens, as shown in the following image.

3. Select the check box in front of Account, Contact, and any other objects you want.
4. Click Create Synonym.

The Status dialog box opens.
5. Ensure that for each synonym you selected, the message Created Successfully appears.
   Click Close.
6. Right-click an application directory and select New, Synonym via synonym editor.
   A blank synonym opens.
7. Click the Modeling View tab. Right-click the workspace and select Insert, Reference to existing synonym.
8. Select Account and click Select. The Account object is added to the workflow.
9. Right-click Account and select Insert, Reference to existing synonym.
The Insert Reference to Existing Synonym as Child of ACCOUNT dialog box opens, as shown in the following image.

10. Select contact and click Select.

**Note:** Under Join Type some of the synonyms have a value Matching primary keys. To create a synonym with a cluster join for salesforce.com objects, you must select one of those synonyms. The Join Condition shown will be used to join to the two objects.
The two objects can now be seen in the modeling view.

11. Click the Save button on the toolbar.

   The Save Synonym As dialog box opens.

   Enter `account_contact` for the name of the synonym and click Save.

12. Click the tab at the bottom of the screen to switch to Field View.
13 Ctrl+click on NAME and then scroll down to the CONTACT segment and Ctrl+click on LASTNAME and FIRSTNAME.

14 Right-click and select Sample Data.

The report appears showing the Account Name and the contact Last Name and First Name.
Syntax: How to Control the Retrieval of Deleted Records

You can control whether or not deleted and archived records are retrieved from salesforce.com.

ENGINE SFDC SET SHOWDELETED{YES|NO}

where:

SFDC
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

YES
Deleted and archived records are included in the records displayed.

NO
Deleted and archived records are not retrieved. This is the default.

Syntax: How to Control the Block Size

You can control the number of records retrieved from salesforce.com in one block.

ENGINE SFDC SET BLOCKSIZE nnnn

where:

SFDC
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
The number of records to retrieve in a block. The default is 200. The maximum is 9999.
The Adapter for SAP BW allows WebFOCUS for SAP Business Intelligence Warehouse (BW) and other applications to access SAP BW data sources through the SAP BW multi-dimensional (OLAP) model. The adapter converts data or application requests into native SAP BW statements and returns optimized answers sets to the requesting program.

**Topics:**

Preparing the SAP BW Environment

In this section:
Accessing Multiple Systems

Reference:
List of Authorization Objects, Fields, and Required Values

SAP BW remote communications require:

- SAP BW BASIS 6.4 or higher and SAP BW 3.1C or higher.
- Installation of the SAP RFC/SDK 4.6 or higher on the Server system.
  The Server requires the SAP RFC SDK to communicate with the SAP Application Server.
  The location of the RFC SDK depends on the platform specific search path.

Platform dependent search path for shared libraries (RFC SDK):

- **Windows:**
  - Directory where the executable is located.
  - Current directory.
  - Windows system directory and Windows directory.
  - Environment variable PATH.

- **AIX:**
  - Environment variable LIBPATH.

- **On z/OS:**
  - Environment variable LIBPATH.

- **All other UNIX platforms:**
  - Environment variable LD_LIBRARY_PATH.
  
  If the server does not start, and indicates that some NLS libraries cannot be found, try:

  ```
  EXPORT NLSUI_7BIT_FALLBACK=YES
  ```
SAP BW 3.5 users. SAP Note 11682 has been implemented. Required environment settings include:

On all platforms (RFCSDK points to the SAP RFC SDK Shared libraries):

```bash
SAP_HOME=$RFCSDK/lib
```

On Solaris (for other platforms, please read OSS note 11682 for defining path):

```bash
LD_LIBRARY_PATH=$SAP_HOME
```

If the server does not start, and indicates that some NLS libraries cannot be found, try:

```bash
EXPT LSLUI_7BIT_FALLBACK=YES
```

Support for IBM iSeries platform. This release introduces support for RFCSDK 640E as of OS Release V5R2 on SAP R3 and BW. When configuring the adapter, the RFCSDK 640E must be specified/added to the current library list.

Related adapter configuration options for SAP R3 and BW on IBM platforms can be found in *How to Configure the Adapter in a z/OS (USS) and iSeries environments* and *Supporting Mixed Code Page Environments* in the SAP R3 and SAP BW sections of the WebConsole online help system or the *Adapter Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS* manual.

A TCP/IP connection to the SAP BW source system.

The following SAP Authorization profiles are required at a minimum. This list may change depending on your SAP BW Release and/or site specific Authorization Profiles.

### Accessing Multiple Systems

The query adapter can operate across multiple BW systems. For each system, the query adapter requires one BW logon consisting of client, user, and password. This logon must be:

- RFC-enabled.
- Authorized for all clients that you may access.
Authorizations in SAP-BW are specific to the local security policy. In addition to the authorizations documented in this manual, additional authorizations will be required in most instances. Please contact your SAP-BW basis administrator.

**Configuring the Adapter for SAP BW**

**In this section:**
Declaring Connection Attributes

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In addition, for SAP BW running on z/OS, you must install the SAP Code Page on the BW application server.

**Declaring Connection Attributes**

**How to:**
Declare Connection Attributes
Configure the Adapter on IBM Systems Using EBCIDC Character Sets

**Reference:**
Connection Attributes for SAP BW

In order to connect to the SAP BW Application Server, the adapter requires connection and authentication information, which is supplied using the SET CONNECTION_ATTRIBUTES command.

You can enter connection and authentication information on the Configuration pane of either the Web Console or the Data Management Console. The global server profile (edasprof.prf), a user profile (user.prf), or a group profile will be updated with the adapter connection attributes.

You can declare connections to more than one SAP BW data source by including multiple connections. The actual connection to SAP BW takes place when the first query that references the connection is issued. If more than one connection is declared, the adapter uses the attributes specified in the last connection.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
From the Data Management Console, expand the Adapters folder.
The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for SAP BW
The SAP BW adapter is under the OLAP group folder.
The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.
The major work of the query adapter is to translate the user request into code that can be understood by SAP BW.

System
Name of the connection; maximum 12 characters.

Connection Parameters
The Load Balancing check box determines which of the following options is exposed.

GROUP
Name of the application group. An application group defines a list of application servers on which an RFC application can be running. R/3 transaction SMLG can be used to view or modify application groups.

Note that the entries are case-sensitive and blank spaces are significant.
Appears only when Load Balancing is checked.

MSGHOST
Host name of the SAP system (message server).
Appears only when Load Balancing is checked.
**R3NAME**

System ID of the SAP system.
Appears only when Load Balancing is checked.

**HOST**

Host name of the SAP application server.

**GWHOST**

Host name of the machine where the SAP gateway process is running. In the case where there is only one SAP application server, gwhost and host is the same.

**SYSNR**

SAP system number. This is a 2-digit numeric value. Obtain this value from the SAP Administrator.

**CONNECTION LANGUAGE**

For SAP BW Unicode configurations, you can select a language that is different from the language you use when logging on to the server (as determined by your NLS configuration).

From the CONNECTION LANGUAGE drop-down list on the Add SAP BW non Unicode to Configuration pane, select the language you wish to use to connect to SAP BW.

**Note:**

- When the CONNECTION LANGUAGE option is used to specify a language other than the one used for logging in to the server, the Create Synonym Multilanguage option is not available.

- For this option to work, the codepage of the iWay server must match the codepage of the SAP BW server. For example, if the iWay server is configured FOR codepage 942 (SJIS), the SAP server must be configured for codepage 8000.

- There is no way to check if the requested connection language can be used by either the iWay server code page (either in terms of display or number of bytes) or the SAP BW server.

**SAP Security Mode**

When SNC is checked, you must specify values for the following additional parameters:

**SNC_LIB**

SNC_LIB contains the path to the external security product library. The external security product library, external library, SNC_LIB, or gssapi library contains the functions provided by the external security product certified by SAP.
Set the environment variable SNC_LIB to contain the path to the security product library.

<drive>:\path\to\your\snclib.dll

**SNC_PARTNERNAME**

Is the external name of the SAP system. This is an extended version of the external name called the SNC name. You create the SNC name by providing a prefix with the external user name that designates the name type entered as follows:

<SNC-name_of_SAP_AppServer>

For example:

p/secude:CN=miller, OU=ADMIN, O=SAP, C=DE
p/krb5:miller@WDF.SAP-AG.DE

**Note: SNC with load-balancing.** Load-balancing, or group-logon, dynamically retrieves the target SNC-Name from the message server. When using SNC with load balancing, you must specify the following additional parameters:

SNC_PARTNERNAME=p:unused
SNC_LIB=<drive>:\path\to\your\snclib.dll

Click Configure.

The next step is adding a connection. Click Next to continue.

**General User Login Parameters**

**Security**

There are three methods by which a user can be authenticated when connecting to an SAP BW instance:

- **Explicit.** The user ID and password are specified for each connection and passed to SAP BW for authentication and request execution. (When you select Explicit, the USER and PASSWORD options are displayed.)

- **Password Passthru.** The user ID and password received from the client application are passed to SAP BW for authentication and to execute the user request.

- **Trusted.** Is set automatically when SNC is selected.

**CLIENT**

SAP BW Client for the user logon; maximum three characters.

**USER**

SAP BW user ID for the user logon.

**PASSWORD**

SAP BW password for the user logon; maximum 40 characters.
For more information, see *Preparing the SAP BW Environment* on page 2064.

**Note:** If the SAP BW system is running in a z/OS (USS) environment, see *How to Configure the Adapter on IBM Systems Using EBCIDC Character Sets* on page 2072.

**Procedure:** How to Configure the Adapter on IBM Systems Using EBCIDC Character Sets

To configure the adapter on IBM systems using the EBCIDC character set, the following code pages must be installed on the BW application server:

- In a z/OS environment, SAP code page 0126.
- For iSeries, SAP code page 0123.

1. Create two conversion tables as described in *Supporting Mixed Code Page Environments* on page 2072, and transfer the tables to the $EDACONF/etc directory.
   
   For example, if the Server environment uses the code page 1100, then two conversion tables, 11000126.CDP and 01261100.CDP, should be created and transferred to the $EDACONF/etc directory.

2. The following environment variables are required at run time:

   ```
   export SAP_CODEPAGE=0126
   export PATH_TO_CODEPAGE=$EDACONF/etc/
   ```

   **Note:** Make sure to include the trailing "/" for the value of the PATH_TO_CODEPAGE parameter.

**Supporting Mixed Code Page Environments**

In this section:

- Character Conversion Tables

If you are using an SAP server that supports unicode, the adapter must also be configured for unicode. With this configuration, no character conversion tables are required.
If, however, you are using an older SAP server that does not support unicode the following information applies. SAP BW, as well as adapters, can be installed on various platforms. If SAP BW is installed on a platform that uses a code page or character set different from the adapter platform, two character conversion tables must be generated to translate the different character sets, one for each direction of data flow. For example, suppose that SAP BW is installed on an IBM i EBCDIC machine and the Adapter for SAP BW is installed on an Intel Windows ASCII machine. If a request is going from the server to SAP BW, an ASCII to EBCDIC translation is required. If SAP BW is sending data back to the Adapter for SAP BW, an EBCDIC to ASCII translation is required. This section describes how to create conversion tables and where they must reside.

**Character Conversion Tables**

**How to:**
- Generate Conversion Tables
- Download the Conversion Tables to the Server

SAP BW provides a transaction, SM59, to generate conversion tables for RFC-based applications such as the Adapter for SAP BW. Once these tables are created, they must be copied to the adapter.

**Procedure:** **How to Generate Conversion Tables**

1. Type transaction SM59 at the SAP GUI command line.
The following window opens.

2. Select the Generate Conv. Tab option from the RFC pull-down menu.
The following window opens.

### 3. Type a value for the Source code page, Target code page, and a valid path on the application server where the conversion table file is created. Optionally, you can supply a valid path and a unique file name.

### 4. Click **Execute**.

If you did not specify a unique file name, the default file name of the newly created conversion table will contain the source and target code page values. For example, if you specified a source code page of 0102 (IBM i for some CUAs) and a target code page of 1101 (7 bit USA ASCII pur), the default file name is 01021101.cdp. This is your IBM i (EBCDIC) to ASCII conversion table file.

It is now necessary to create another conversion table file for translating code pages in the opposite direction.

### 5. Switch the source and target code pages and generate the conversion table.

Continuing with previous example, you should have a source code page of 1101 and a target code page of 0102, resulting in a default file name of 11010102.cdp. This is your ASCII to IBM i (EBCDIC) conversion table file.
Note: If a unique file name was used for the first conversion table, be sure you specify a unique file name for the second conversion table.

Procedure: How to Download the Conversion Tables to the Server

Once these conversion table files are created, you can download them from the SAP application server directory to the server configuration ETC directory. Use SAP BW transaction AL11 to browse and download the two conversion table files to a local file on the desktop or Windows machine where the server is installed. Note that SAP GUI is required on the machine to which you are downloading the conversion table files. The following window represents transaction AL11.

1. Double-click the directory where the conversion table files were created.
The following window opens.

![Error Log Files window]

2. Double-click the conversion table file to view its contents.
3. Select the List option from the System pull-down menu and select Save to Local File, as shown in the following image.

![Screen shot showing the System pull-down menu and the List option selected.]

A dialog box displays prompting on a format for the transfer file.

4. Select unconverted format and click Continue.

5. Type a valid file name and click Transfer. This transfers the file to your local desktop.

6. Use any available editor on your desktop and remove the first three lines from the conversion table file. The following is an example of the text that should be removed:

   ```
   Directory /tmp
   Name: 01021102.CDP
   -----------------------------------------------
   ```

After the edits have been made, configure the server with the Adapter for SAP BW. Once the adapter is configured, the conversion table files must be moved to the server EDAHOME ETC directory. Make sure both conversion table files are moved.
Creating BEx Queries

In this section:
- SAP BW Terminology
- BEx Query Terminology
- Defining New Business Explorer Queries
- Restricting Query Characteristics
- Restricting and Calculating Key Figures
- Viewing Query Properties and Releasing for OLAP

The adapter can report against several types of SAP BW objects, some of which represent views or subsets of the actual data. Using the Business Explorer (BEx) provided by SAP as its reporting and analysis tool, you can create queries (methods for extracting data) and reference them in WebFOCUS report requests.

A query is a subcube created by selecting characteristics and key figures. Using queries, the data can be quickly targeted and evaluated. The more precisely the query is defined, the smaller the subcube and the quicker the query can be navigated and refreshed. Selecting certain characteristics means that they can be more closely analyzed while others remain unspecified. The resulting key figures are aggregated across all characteristic values for the unspecified characteristics.

A default navigational state is also established in the query definition when you arrange the characteristics and key figures in the rows and columns of the query.

Only the data that is currently requested is transferred to the query. The OLAP processor builds the query from the data and provides methods for navigating through the data in several dimensions. Since a query preselects information, the same data can yield dramatically different results depending on the query used to view its contents.

SAP BW Terminology

The Business Explorer (BEx) is the SAP BW component that provides reporting and analysis tools. BEx queries filter the data to create reporting objects or views called InfoProviders. Some InfoProviders contain actual data. Others provide views of data stored in elsewhere.

The basic elements used to define InfoProviders are called InfoObjects. An InfoObject is a business evaluation object, such as customer or sales revenue, relevant to your analysis of business performance. InfoObjects can be characteristics (dimensions), key figures (measures or facts), units, time characteristics, or technical characteristics (for example, request number).
The following InfoProviders can be used for WebFOCUS reporting:

- **InfoCube.** An InfoCube is a self-contained set of business data. The physical data store is called the BasicCube. It consists of InfoObjects and is structured in a star schema, which means that one large fact table contains the key figures (numeric data values). This fact table is surrounded by smaller dimension tables that store characteristics (categories of data). Other types of InfoCubes display logical views of a data set. Some examples follow.

  - **RemoteCube.** A RemoteCube is an InfoCube whose transaction data is not managed by BW, but externally.

  - **SAP RemoteCube.** An SAP RemoteCube is a RemoteCube for which you can define queries by accessing transaction data in other SAP systems.

  - **Virtual InfoCube with Services.** A Virtual InfoCube with Services is an InfoCube whose data is not stored in BW and for which a user-defined function module is used to retrieve the data.

- **ODS Object.** An ODS object is a set of cleaned up transaction (detail level) data. It contains key fields (for example, item number) and data fields (such as order status or customer).

- **InfoSet.** An InfoSet is a join between ODS objects and/or InfoObjects. It is a definition of the conditions that determine how the objects should be joined.

- **MultiProvider.** A MultiProvider is a combination of data from separate InfoProviders. It does not contain data; data comes from the separate InfoProviders.

An **InfoObject catalog** is an application-specific organization of InfoObjects, either characteristics or key figures.

To report against a cube, you must create a BW synonym that describes it to the adapter. To create a synonym for a query cube, you first create the BEx query. In the query properties, set the Extended Query Properties to Allow external access to this Query.

### BEx Query Terminology

The basic building blocks of a query cube are:

- **Characteristics.** Characteristics, also called dimensions, are classifications such as Region or Time, that you use to analyze and compare business performance.

- **Attributes.** Attributes, also called properties, are additional information about a characteristic. For example, the material characteristic might have attributes such as color or weight.

- **Key Figures.** Key figures, also called measures or facts, are quantifiable values used in evaluating performance. An example of a key figure is sales revenue.
Calculated Key Figures. These key figures are not stored in the data. They are defined in the BEx query and evaluated at run time.

Restricted Key Figures. These key figures are filtered by selecting one or more characteristics. They can be filtered versions of basic key figures, calculated key figures, or other restricted key figures.

Hierarchies. Hierarchies are groupings of characteristics according to individual evaluation criteria. For example, a customer characteristic can be grouped by geographical location, industry, or some other criteria. A characteristic can have multiple hierarchies.

Variables. Variables are parameters of a query. They are set in the query definition and may get their values in different ways. For example, some variables are given default values and others require the user to enter a value. For more information about variables, see Variable Types on page 2164 and Reporting With Variables on page 2136.

Filters. Filters are used to restrict the output of a request. Although not included in a WebFOCUS synonym, they affect the outcome of a WebFOCUS request.

Defining New Business Explorer Queries

How to:
Select an InfoProvider to Query
Create a Query
Filter a Query

You must define an SAP Business Explorer query before reporting from an SAP BW InfoProvider. This query serves as a template for data extraction from the cube.

Note: The information that follows is based on SAP BW Business Explorer documentation. SAP BW BEx documentation is available from http://help.sap.com.

Procedure: How to Select an InfoProvider to Query

1. The Business Information Warehouse must contain at least one InfoProvider before you can define a new query. Start the Business Explorer Analyzer.
2. From the BEx toolbar, choose Open.
   You will see the selection screen for all existing workbooks.
3. Choose Queries.
   The selection screen displays all available queries.
   You will see the selection screen for all InfoProviders for which you can define a new query or queries.

5. Select the InfoProvider that has the data on which the query should be based. To display technical names for InfoProviders, set the Technical name on/off icon to On.
   The available objects in the InfoProvider you have selected are displayed as a directory tree in the left part of the screen.

   Next, you will select the objects for the query and drag them to the appropriate boxes to build the query.

**Procedure: How to Create a Query**

The right area of the BEx screen contains selection boxes for the filter selection, the rows, the columns, and the free characteristics of the query.

Perform the following steps to create a query:

1. Click the plus or minus sign to the left of the dimension or Key Figures you want to query.
   The object list will expand and display a list of all the available Key Figures or characteristics.

2. Drag and drop characteristics and Key Figures from the InfoProvider into the selection box of the query definition.
   These may be filters, rows, columns, and free characteristics.

**Procedure: How to Filter a Query**

You can filter queries in order to place restrictions on them. Filter selection restricts the entire query. To select fields you want to use to filter the query, complete the following:

1. From the object list of the InfoProvider, select the characteristics or the key figure upon which the query should be based.
   **Note:** Since they are used in definitions, fields selected as filters are not displayed in the Adapter for SAP BW metadata. They are used to screen the data and thus contain no information to be reported on. If you wish to screen data and report from it, see *Restricting Query Characteristics* on page 2083 or *Restricting and Calculating Key Figures* on page 2083.

2. Drag the object to the Filter box.

3. Right-click the object in the filter box. A dialog box opens showing the possible filter definitions for the object.
4. Select either a single member, a range of members, or a variable for the filter.

Restricting Query Characteristics

**How to:**
Restrict Characteristics

When defining a query, you may restrict characteristics to a single characteristic value, a value interval, a hierarchy node, or a characteristic value variable.

**Procedure:** How to Restrict Characteristics

1. Choose the characteristic from the InfoProvider for which you want to select a value range.
2. Drag the characteristic into the appropriate selection box of the query definition (rows or free characteristics).
3. Select the characteristic you wish to restrict (or filter). Using the right mouse button, select Restrict from the Context menu.
4. Choose whether you want to restrict the characteristic to a single value, a value interval, or a hierarchy node.
   **Tip:** You can enter the characteristic values or hierarchy nodes you want to use, or you can display a list of all possible values by clicking the magnifying glass to the right of the input field.
5. Confirm your entries by clicking OK.

Restricting and Calculating Key Figures

**How to:**
Restrict Key Figures
Calculate Key Figures
Define a Formula

You can restrict Key Figures to characteristic values, characteristic value intervals, or hierarchy nodes. For example, a restricted key figure would be Sales revenue in 1st quarter.
You can also restrict the Key Figures of the InfoProvider for the query definition, or, using a formula, you can calculate new Key Figures from the (basic) Key Figures:

- **Restricted Key Figures.** (Basic) Key Figures for the InfoProvider that are restricted (filtered) by selecting one or more characteristics.

- **Calculated Key Figures.** Formulas that consist of (basic) Key Figures for the InfoProvider and/or calculated Key Figures that have already been created.

**Procedure: How to Restrict Key Figures**

1. Drag a (basic) key figure into the key figure selection box. Alternatively, select the header of the selection box for rows or columns and, using the right mouse button, select **New Structure** from the Context menu.

2. Select the Structure directory, and, using the right mouse button, choose **New Selection** from the Context menu. The New Selection screen opens.

3. Enter a description of the restricted key figure in the text fields located in the upper part of the screen.

4. Underneath the text fields, on the left, is the directory of all the objects available in the InfoProvider. Use the empty field on the right-hand side of the screen for the definition of the new selection.

5. Using drag and drop, choose a key figure from the InfoProvider, and restrict it using a selection of one or more characteristic values.

6. Select **OK**. The newly restricted key figure is defined in the structure.

**Procedure: How to Calculate Key Figures**

1. Create a new structure in the rows or columns of the query definition by highlighting the row or column directory using the right mouse button and selecting **New Structure** in the Context menu.

2. Drag a (basic) key figure of the InfoProvider into the directory of the new structure.

3. Select the Structure directory, and choose **New Formula**. The Formula Definition screen opens.

4. Enter a description of the formula in the text fields located in the upper part of the screen.

**Note:** The entry field for the formula is underneath the text fields. In the bottom left of the screen are all of the operands available for the formula definition. These are the Key Figures that you have already defined in the structure, and all of the formula variables in the Variables directory that have been created in the variable maintenance.
The functions available as operators are on the right-hand side of the screen. These are symbols for the basic arithmetic operations and directories with calculation functions such as percentage or trigonometric functions. To the right of the operators is a number block.

**Procedure: How to Define a Formula**

1. Choose the operands you want to use, and insert them in the entry field for the formula by double-clicking or by using drag and drop.
2. Choose the calculation functions you want to use by either clicking the symbols for the basic arithmetic operations, double-clicking to select the individual values, or dragging the entire key figure into the formula box.
3. Select the number values for the formula by clicking the number block.
4. Define your formula using the available operands and operators.
   - If you want to use a variable that is not contained in the operands, you must create the variable first.
5. Check the formula definition for correctness by pressing the scale icon.
6. Enter the name of the formula column in the description box.
7. Select OK. The newly calculated key figure is defined in the structure.

**Viewing Query Properties and Releasing for OLAP**

- To view the properties of a query, click the Query Properties icon on the toolbar. The Query Properties dialog box opens.
- To release a query for OLAP, click the Query Properties icon on the toolbar and check the following in the Query Properties dialog box:
  - *Allow External Access* (for SAP BW releases 3.x and higher).
  - *Release for OLE DB for OLAP* (for SAP BW releases prior to 3.x).

This enables the query to be displayed as a QUERY_CUBE for reporting purposes. The query elements (hierarchy levels, measures, variable, and properties) will be mapped to corresponding OLAP elements to create a synonym.

Creating Dynamic Dimensions

Overview of SAP BW Reporting Concepts

In a multi-dimensional data source (cube), dimensions (called characteristics in SAP BW) are categories of data, such as Region or Time, that you use to analyze and compare business performance. Dimensions consist of data elements that are called members. For example, a Region dimension could have members England and France.

Dimension members are usually organized into hierarchies. Hierarchies can be viewed as tree-like graphs where members are the nodes.

For example, the Region dimension may have the element World at its top level (the root node). The World element may have children nodes (members) representing continents. Continents, in turn, can have children nodes that represent countries, and countries can have children nodes representing states or cities. Nodes with no children are called leaf nodes.

Measures (also called key figures in SAP BW) are numerical values, such as Sales Volume or Net Income, that are used to quantify how your business is performing.
A multi-dimensional cube consists of data derived from facts, which are records about individual business transactions. For example, an individual fact record reflects a sales transaction of a certain number of items of a certain product at a certain price, which occurred in a certain store at a certain moment of time. The cube contains summarized fact values for all combinations of measures and members of different dimensions.

For example, the following combination (tuple) contains the total volume of sales of pumps in all stores in England in 2005:

\{Sales Volume, Pumps, England, 2005\}

The point in the cube that contains this summarized value is called a cell. A cell is addressed by a combination of members of different dimensions and a measure. In this example Sales Volume is a measure and Pumps, England, and 2005 are members of the Product, Region, and Time dimensions respectively.

Individual fact records are usually tied to the leaf nodes of each hierarchy in the cube. The fact values get included in cells addressed by these leaf nodes and added to all cells addressed by all combinations of ascendants of these leaf nodes along each hierarchy of the cube.

The operation used to summarize facts for some measures can be a simple sum or a more complex aggregation function such as an average.

It often happens that some combinations of hierarchy nodes do not have any fact records tied to them. The cells addressed by these combinations are empty cells.

As illustrated in the previous example, a tuple is a combination of members from different dimensions of a cube. The previous tuple contains members from all dimensions and, therefore, addresses a single cell. If a tuple contains only members from some dimensions, it addresses not just one cell but a whole slice of cells in the cube. For example, the following tuple does not include either Region or Time dimension members:

\{Sales Volume, Pumps\}

It addresses as many cells in the cube as there are members of the Region dimension times the number of members of the Time dimension.

The number of cells in the cube addressed by a single dimension member is a product of cardinalities of all other dimensions.

When all cells addressed by a member are empty, the member is called an empty member. When all cells addressed by a tuple are empty, the tuple is called an empty tuple.

By default, empty cells do not appear on report output. You can issue the following command if you want them on the report output:

\texttt{ENGINE BWBAPI SET EMPTY ON}
BW cubes can also include variables, which are parameters used in data selection. Variables cannot be displayed or used for sorting; they can only be used in selection criteria. A variable can be defined as mandatory or optional. If a variable is mandatory, the request must contain a WHERE test using that variable. The WHERE criteria must provide the type of restriction required based on the variable selection type, for example, a single value (using an equality test) or an interval (using a FROM/TO or GE/LE test).

When the adapter accesses a multi-dimensional cube, it uses two types of metadata elements about dimensions:

- **Hierarchy fields.** These fields contain data that apply to a specific hierarchy and describe each member’s position within that hierarchy. For example, these fields identify the member’s parent as well as its own name, caption, unique ID, and level number.

- **Dimension properties.** These fields contain data that potentially apply to all members of the dimension. For example, a Region dimension may have a property called GEOGRAPHICAL_HEIGHT that specifies the altitude for each member of the Region dimension.

Using the hierarchy fields, the adapter can recreate the hierarchy and locate portions of the hierarchy needed to satisfy a request.

### Understanding Columnar and Hierarchical Reporting

**Reference:**

Prerequisites for Hierarchical Reporting

Two types of hierarchy can be represented in a synonym: level and parent/child.

A synonym describes a level hierarchy by using a separate field for each level. To report on a level hierarchy, you use *columnar reporting* in which you specify the field name for each level you want to display.

A synonym describes a parent/child hierarchy using a set of fields that define the hierarchical structure and the relationships between the hierarchy members. The adapter has special *hierarchical reporting* syntax for reporting on parent/child hierarchies.

**Note:** When you create a synonym, you can choose whether to describe the parent/child hierarchies in this way or as level hierarchies, with a separate field for each level.

Hierarchical reporting enables you to sort and select members of parent/child hierarchies without knowing specific level numbers.

A hierarchical reporting request goes through several phases before output is displayed.
Hierarchical Sorting and Member Selection

The first phase selects hierarchy members to display. The hierarchical reporting phrase BY or ON HIERARCHY automatically sorts and formats a hierarchy with appropriate indentations that show the parent/child relationships. If you do not want to see the entire hierarchy, you can use the WHEN phrase to select hierarchy members for display. The expression in this WHEN phrase must reference only hierarchy fields, not dimension properties or measures.

Dimension properties and measures are linked to the leaf nodes of the dimension and, therefore, cannot be used in selecting hierarchy levels for display.

Screening Dimension Data

Once hierarchy members are selected, you can screen the retrieved dimension data by applying WHERE tests to the selected members.

WHERE criteria are applied to the leaf nodes and are processed after the phase of the request that selects hierarchy members. Therefore, dimension properties can be used in WHERE tests.

These tests can also reference hierarchy fields. However, since the selection criteria are always applied to the values at the leaf nodes, they cannot select data based on values that occur at higher levels. For example, in a dimension with Continents, Countries, and Cities, your request will not display any rows if you use WHERE to select at the Country level, but it may if you use it to select at the City level.

Screening Based on Aggregated Values

Measures, being summarized values, can be referenced in WHERE TOTAL tests and COMPUTE commands because those commands are processed after the hierarchy selection and aggregation phases of the request. When screening with WHERE TOTAL, the aggregation phase of the report processing is over, so totals on the report are not recalculated to account for the data that is screened out, the rows are just removed.

Reference: Prerequisites for Hierarchical Reporting

Hierarchical reporting uses special metadata attributes and reporting syntax. You must:

- Create a synonym that describes hierarchies as parent/child relationships.
- Use hierarchical reporting syntax in your request to automatically build and format hierarchies in the report output.

For more information on creating synonyms, see Creating Synonyms on page 2153. For more information on hierarchical reporting, see Hierarchical Reporting on page 2096.
Representing Hierarchies in a Synonym

Example:
- Dimension Declaration
- Describing a Level Hierarchy
- Describing a Parent/Child Hierarchy
- Dimension Properties
- Sample Request Using a Level Hierarchy
- Sample Request Using a Parent/Child Hierarchy

Dimensions are organized into sets of hierarchies. For example, in a Time dimension, years, quarters, and months can form a hierarchical or parent/child relationship. This means that the measures for each month are aggregated into values for quarters, and the quarters are aggregated into values for years. Each point in the hierarchy is called a node. Nodes at the bottom of the hierarchy (with no children) are called leaf nodes.

According to the OLAP model, each dimension has one hierarchy called the flat hierarchy. This hierarchy contains all leaf node members of the dimension as the children of the root node named ALL (which is not assigned a field name in the synonym). In a synonym, the flat hierarchy is assigned the same name as the dimension.

In a synonym, hierarchies can be described in one of two ways:

- **Level hierarchy.** Each hierarchy level is described using a separate field name. To issue a report request, you must reference the field name for those levels you want to display on the report output.

  When you create a synonym with level hierarchies, the synonym contains one field declaration for each level. This declaration also specifies which field is its parent. If the data changes to have an additional level, you must recreate the synonym in order to account for this additional field and parent reference.

- **Parent/child hierarchy.** The hierarchy is described with a set of fields that contain values for properties that describe each member position in the hierarchy. For example, there are fields to contain a member’s unique ID, level number, its parent, and the parent member level number. To issue a report request, you only need to specify the field name of one of the hierarchy fields.

  With a parent/child hierarchy, one set of field names in the synonym describes the hierarchy. A change in the number of levels does not require a change to the synonym.

  Another advantage of parent/child hierarchies is that the adapter can recreate and format any portion of the hierarchy. The request does not have to specify level numbers.
**Note:** The flat hierarchy is always defined as a level hierarchy with one level.

Dimension properties apply to all hierarchies in the dimension and are listed in the synonym following all of the dimension’s hierarchies. Most of the examples in this topic use synonyms named ZOPT and ZLEVEL created using the cube OSD_C01/ZTSCQ31CQ1.

**Example: Dimension Declaration**

Each dimension begins with a dimension record that defines the dimension and its hierarchies. The dimension itself is level zero. In this example, only the Material Class hierarchy was selected to be part of the synonym. However, there is always a flat hierarchy with the same name as the dimension. The flat hierarchy contains a member list of leaf nodes and is always defined as a level hierarchy, so two hierarchies are listed in the [OMATERIAL] dimension.

Dimension:

```
DIMENSION=[OMATERIAL], CAPTION='Material', $
```

Flat hierarchy, same caption as the dimension:

```
HIERARCHY=[OMATERIAL], CAPTION='Material'... $
```

Material Class hierarchy:

```
HIERARCHY=[OMATERIAL 001], CAPTION='Material class' ...
```

**Example: Describing a Level Hierarchy**

Each level of the hierarchy is assigned a field name consisting of the hierarchy name (for example, MATERIAL_CLASS) with the level number appended. Each field declaration also specifies the field name of its parent with the WITHIN attribute. The value stored in this field is the member's caption (title).

For the level 1 field MATERIAL_CLASS_LEVEL_01, the parent is the MATERIAL_CLASS dimension.

For the level 2 field MATERIAL_CLASS_LEVEL_02, the parent is MATERIAL_CLASS_LEVEL_01.

If a new level appears in the data, the synonym must be recreated to define this new level. The cardinality for each level is its number of members.

The following field describes level three. Its parent is level 2:

```
[0MATERIAL 001].[LEVEL03] Cardinality 86
FIELDNAME=MATERIAL_CLASS_LEVEL_03, ALIAS=LEVEL03, USAGE=A40, ACTUAL=A40, MISSING=ON,
TITLE='Material class',
WITHIN=MATERIAL_CLASS_LEVEL_02,
PROPERTY=CAPTION, $
```
The following field represents the flat hierarchy. There are two fields associated with this hierarchy. The first contains the member caption and the second contains the member name:

```plaintext
FIELDNAME=MATERIAL_LEVEL_01, ALIAS=LEVEL01, USAGE=A40, ACTUAL=A40,
MISSING=ON,
TITLE='Material Member Caption',
WITHIN='*[OMATERIAL]',
PROPERTY=CAPTION, $
FIELDNAME=MATERIAL_NAME, ALIAS=MEMBER_NAME, USAGE=A18, ACTUAL=A18,
MISSING=ON,
TITLE='Material Member Name',
REFERENCE=MATERIAL_LEVEL_01, PROPERTY=NAME, $
```

**Example: Describing a Parent/Child Hierarchy**

Several fields are used to define a parent/child hierarchy. Each has a PROPERTY attribute that describes which hierarchy property it represents. The hierarchy field names are formed by appending a suffix to the hierarchy name.

For example, the caption of a hierarchy named MATERIAL_CLASS is stored in a field whose name is MATERIAL_CLASS_CAPTION and whose property attribute is PROPERTY=CAPTION.

The following table describes the hierarchy fields:

<table>
<thead>
<tr>
<th>Description of Data</th>
<th>PROPERTY=</th>
<th>Field Suffix</th>
</tr>
</thead>
<tbody>
<tr>
<td>Member Unique ID (unique</td>
<td>UID</td>
<td>none</td>
</tr>
<tr>
<td>within the cube)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Member Name (unique within</td>
<td>NAME</td>
<td>_NAME</td>
</tr>
<tr>
<td>the hierarchy)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Member Level Number</td>
<td>LEVEL_NUMBER</td>
<td>_LVLNO</td>
</tr>
<tr>
<td>Member Parent</td>
<td>PARENT_OF</td>
<td>_PARENT</td>
</tr>
<tr>
<td>Parent Level Number</td>
<td>PARENT_LEVEL_NUMBER</td>
<td>_PARENT_LVLNO</td>
</tr>
<tr>
<td>Number of Children</td>
<td>CHILDREN_CARDINALITY</td>
<td>_CHILDREN_CARD</td>
</tr>
<tr>
<td>Member Caption (title on</td>
<td>CAPTION</td>
<td>_CAPTION</td>
</tr>
<tr>
<td>reports)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The following declaration for the MATERIAL_CLASS hierarchy describes the field that contains the unique ID of a member (PROPERTY=UID):

```plaintext
FIELDNAME=MATERIAL_CLASS, USAGE=A143, ACTUAL=A143,
    MISSING=ON,
    TITLE='Material class',
    WITHIN='*[0MATERIAL                     001]',
    REFERENCE=[0MATERIAL], PROPERTY=UID, $
```

The following declaration for the MATERIAL_CLASS hierarchy defines the field that contains a member title (PROPERTY=CAPTION):

```plaintext
FIELDNAME=MATERIAL_CLASS_CAPTION, USAGE=A60, ACTUAL=A60,
    MISSING=ON,
    TITLE='Material class CAPTION',
    REFERENCE=MATERIAL_CLASS, PROPERTY=CAPTION, $
```

Each parent/child hierarchy has three additional fields defined to make reports easier to read:

- The key (field name suffix _KEY). The key is the first token in the member name.
- The key and caption separated by a blank (field name suffix _KEY_CAP).
- The caption and key separated by one blank (field name suffix _CAP_KEY).

For example, for the MATERIAL_CLASS hierarchy, the DEFINE fields are named:

- MATERIAL_CLASS_KEY
- MATERIAL_CLASS _KEY_CAP
- MATERIAL_CLASS_CAP_KEY

**Example: Dimension Properties**

Following all of a dimension hierarchies, the dimension properties (called attributes in SAP BW) are described. Each of these has PROPERTY=UDA (User Defined Attribute) in the synonym. For example the following field represents a member’s net weight property:

```plaintext
FIELDNAME=NET_WEIGHT__KEY_, ALIAS='20NET_WEIGHT', USAGE=A9, ACTUAL=A9,
    MISSING=ON,
    TITLE='Net weight (Key)',
    REFERENCE=[0MATERIAL], PROPERTY=UDA, $  
```
**Example: Sample Request Using a Level Hierarchy**

A report request against a level hierarchy must specify the field name for each level of the hierarchy required in the report. For example, the following request displays the sales volume measure for levels one through three of the Material Class hierarchy:

```
TABLE FILE ZLEVEL
SUM SALES_VOLUME
BY MATERIAL_CLASS_LEVEL_01 AS 'LEVEL1'
BY MATERIAL_CLASS_LEVEL_02 AS 'LEVEL2'
BY MATERIAL_CLASS_LEVEL_03 AS 'LEVEL3'
ON TABLE COLUMN-TOTAL
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
END
```

The output is:

<table>
<thead>
<tr>
<th>LEVEL1</th>
<th>LEVEL2</th>
<th>LEVEL3</th>
<th>Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>Products</td>
<td>Computer systems</td>
<td>Computer accessories</td>
<td>67,967,525.71</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Computer hardware</td>
<td>17,874,768.15</td>
</tr>
<tr>
<td>Paints / aux and operating supplies</td>
<td>Pumps</td>
<td>Pumps (complete)</td>
<td>59,367,205.93</td>
</tr>
</tbody>
</table>

**TOTAL** 145,209,499.79

In order to get a total for the entire hierarchy, you have to use an ON TABLE COLUMN-TOTAL command in the request or add another SUM command without a BY phrase (and this would add another column to the report output).
**Example:** Sample Request Using a Parent/Child Hierarchy

A report request against a parent/child hierarchy can use the BY HIERARCHY phrase to report against the entire hierarchy. The output is automatically formatted with appropriate indentations to show the hierarchy levels and relationships. For example, the following request shows the sales volume measure for three levels of the Material Class hierarchy:

```plaintext
TABLE FILE ZOPT
SUM SALES_VOLUME
BY MATERIAL_CLASS.Caption HIERARCHY
SHOW TO DOWN 3
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $ 
END
```

The output is:

<table>
<thead>
<tr>
<th>Material class Member Caption</th>
<th>Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material class</td>
<td>145,209,499.79</td>
</tr>
<tr>
<td>Products</td>
<td>145,209,499.79</td>
</tr>
<tr>
<td>Computer systems</td>
<td>85,842,293.86</td>
</tr>
<tr>
<td>Computer hardware</td>
<td>17,874,768.15</td>
</tr>
<tr>
<td>Computer accessories</td>
<td>67,967,525.71</td>
</tr>
<tr>
<td>Paints / aux. and operating supplies</td>
<td>0.00</td>
</tr>
<tr>
<td>Paints</td>
<td>0.00</td>
</tr>
<tr>
<td>Pumps</td>
<td>59,367,205.93</td>
</tr>
<tr>
<td>Pumps (complete)</td>
<td>59,367,205.93</td>
</tr>
</tbody>
</table>

The report request does not have to reference specific hierarchy levels. The BY HIERARCHY phrase recreates and formats the hierarchy for display. You can also use a WHEN phrase to select a portion of the hierarchy and a SHOW phrase to specify how many levels above and below the selected portion of the hierarchy you want to display. This display format clearly shows the parent/child relationships between the hierarchy members.

In addition, you can specify whether you want the measure values for each parent to represent aggregates for all of its children (full total) or only those selected for display (visual total).

For more information, see *Hierarchical Reporting* on page 2096.
Hierarchical Reporting

**How to:**
Display Parent/Child Hierarchies

**Example:**
Reporting on a Whole Hierarchy
Selecting a Hierarchy Member
Selecting a Member and Adding a Parent
Selecting a Member and Adding Children
Selecting a Member and Showing All Ascendants
Selecting a Member and Showing All Descendants
Selecting a Member and Showing All Ascendants and Descendants
Displaying Members of a Range of Hierarchy Levels
Selecting Members for Display and Screening on Member Values
Comparing Member Selection With Data Screening
Using SHOW Without WHEN
Using SKIP-LINE
Using Sort Options Conditional on a Measure
Using Sort Options Conditional on a Dimension Property
Using Sort Options Conditional on a Hierarchy Field
Using WHERE TOTAL to Screen on a Measure
Using Two BY HIERARCHY Phrases
Using BY HIERARCHY and BY Phrases
Using ON HIERARCHY Without BY HIERARCHY
Using Multiple Display Commands in a Hierarchical Report

**Reference:**
Hierarchical Reports With Multiple Display Commands

When you issue a request against a cube, some of the requirements and features available depend on the type of hierarchy defined in the synonym.
With a parent/child hierarchy, you can specify whether the measure values displayed for each parent should show the sum of all of its descendants (full total) or the sum of its displayed descendants (visual total). For level hierarchies, the report always displays full totals, which are the values actually stored in the cube.

When a synonym defines parent/child hierarchies, you can use the BY HIERARCHY phrase to sort and format the hierarchy. You can also limit the portion of the hierarchy selected for display using the WHEN phrase.

When a hierarchical request is processed, the first step is to build the hierarchy and mark which nodes should be included, which should be excluded, and which are needed for context.

The next stage fills the hierarchy with measure values. This stage applies WHERE criteria at the leaf nodes to further qualify the members selected for the report. Dimension properties cannot be used in the initial selection phase of the request, but can be used to screen the selected rows based on dimension data.

Measure values also cannot be used to select hierarchy levels for reporting. After the hierarchy rows have been selected, screened, and aggregated, WHERE TOTAL tests can limit the rows displayed based on measure values.

**Syntax:**

**How to Display Parent/Child Hierarchies**

The following syntax can be used to generate hierarchical reports when the synonym defines parent/child hierarchies:

```plaintext
SUM [FROLL.]measure_field ...
BY hierarchy_field [HIERARCHY [WHEN expression_using_hierarchy_fields;]
[SHOW [TOP|UP n] [TO {BOTTOM|DOWN m}] [byoption [WHEN condition] ...] ] ]
.
.
[WHERE expression_using_dimension_data]
.
.
[ON hierarchy_field HIERARCHY [WHEN expression_using_hierarchy_fields;]
[SHOW [TOP|UP n] [TO BOTTOM|DOWN m] [byoption [WHEN condition] ...]]
```

where:

**FROLL**

Specifies a full roll-up of the measure. With a full roll-up, the value displayed is the value found in the cube. This value may not reflect the sum of its displayed descendants if some descendants are eliminated from the output based on the WHEN and SHOW options. When FROLL is not specified, the value displayed is a visual total, which means it is the total of the values for its displayed descendants.
Note: If a request uses WHERE criteria to screen out some data, FROLL will not display the value found in the cube. It will display the roll-up of the selected data.

measure_field

Is the field name of a measure.

BY hierarchy_field HIERARCHY

Identifies the hierarchy used for sorting. The field must be a hierarchy field.

ON hierarchy_field HIERARCHY

Identifies the hierarchy used for sorting. The field must be a hierarchy field. The request must include either a BY phrase or a BY HIERARCHY phrase for this field name.

WHEN expression_using_hierarchy_fields;

Selects hierarchy members. The WHEN phrase must immediately follow the word HIERARCHY to distinguish it from a WHEN phrase associated with a BY option (such as SUBFOOT). Any expression using only hierarchy fields is supported. The WHEN phrase can be on the BY HIERARCHY command or the ON HIERARCHY command, but not both.

SHOW

Specifies which levels to show on the report output relative to the levels selected by the WHEN phrase. If there is no WHEN phrase, the SHOW option is applied to the root node of the hierarchy. The SHOW option can be specified on the BY HIERARCHY phrase or the ON HIERARCHY phrase, but not both.

n

Is the number of ascendants above the set of selected members that will have measure values. All ascendants appear on the report to show the hierarchical context of the selected members. However, ascendants that are not included in the SHOW phrase appear on the report with missing data symbols in the report columns that display measures. The default for \( n \) is 0.

TOP

Specifies that ascendant levels to the root node of the hierarchy will be populated with measure values.

TO

Is required when specifying a SHOW option for descendant levels.

BOTTOM

Specifies all descendants to the leaf nodes of the hierarchy will be populated with measure values. This is the default value.
\( m \)

Is the number of descendants of each selected level that will display. The default for \( m \) is BOTTOM, which displays all descendants.

\textbf{byoption}

Is one of the following sort-based options: PAGE-BREAK, REPAGE, RECAP, RECOMPUTE, SKIP-LINE, SUBFOOT, SUBHEAD, SUBTOTAL, SUB-TOTAL, SUMMARIZE, UNDER-LINE. If you specify SUBHEAD or SUBFOOT, you must place the WHEN phrase on the line following the heading or footing text.

\textbf{condition}

Is a logical expression.

\textbf{expression\_using\_dimension\_data}

Screens the rows selected in the BY/ON HIERARCHY and WHEN phrases based on dimension data. The expression can use dimension properties and hierarchy fields. However, the selection criteria are always applied to the values at the leaf nodes. Therefore, you cannot use WHERE to select rows based on hierarchy field values that occur at higher levels. For example, in a dimension with Continents, Countries, and Cities, your request will not display any rows if you use WHERE to select a Country name, but it may if you use it to select a City name.

The following examples illustrate hierarchical reporting using the BY HIERARCHY phrase.
The zoxt Master File was created with parent/child hierarchies by selecting \textit{optimized} as the hierarchy type when creating the synonym, based on the cube OSD_C01/ZTSCQ31CQ1.
**Example: Reporting on a Whole Hierarchy**

The following request produces visual totals (SALES_VOLUME) and full totals (FROLL.SALES_VOLUME). The BY HIERARCHY phrase specifies hierarchical reporting. There is no WHEN phrase to limit the portion of the hierarchy displayed. Also note that the full roll-up is displayed with the prefix FSUM added to the field name. The full total is the same as the visual total for a report on the entire hierarchy:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
   **BY MATERIAL_CLASS.Caption HIERARCHY**
ON TABLE SET PAGE NOPAGE
ON TABLE SET SCREEN PAPER
ON TABLE SET LINES 88
ON TABLE SUBHEAD
   "Reporting on a Whole Hierarchy"
ON TABLE SET STYLE *
   TYPE=REPORT, SIZE=8,$
   TYPE=REPORT, GRID=OFF, WRAP=OFF, $
   TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```
The output is:

## Reporting on a Whole Hierarchy

</tbody>
</table>
Example: Selecting a Hierarchy Member

The following request produces a visual total and full total for the MATERIAL_CLASS hierarchy of the MATERIAL dimension, but limits the members selected for display with the WHEN phrase. Note that the hierarchy member selected is displayed in its context (all ancestors to the root of the hierarchy). However, the ancestors are not requested in the report and are, therefore, displayed with missing data symbols. All descendants of the selected members appear in the report output because the default SHOW option for descendants is BOTTOM:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS.Caption HIERARCHY
WHEN MATERIAL_CLASS.Caption EQ 'Computer hardware';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Hierarchy Member"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $ END
```
## Selecting a Hierarchy Member

</tbody>
</table>
Example: Selecting a Member and Adding a Parent

In the following request, the SHOW option UP 1 TO DOWN 0 added to the WHEN phrase adds the parent (Computer systems) of the selected member (Computer hardware). This parent now contains values for the measures rather than missing data symbols. However, the full total column for the parent contains the sum of all of its descendants, not just the selected Computer hardware member, while the visual total shows the total only for the Computer hardware member:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROM.SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
WHEN MATERIAL_CLASS_CAPTION EQ 'Computer hardware';
SHOW UP 1 TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding a Parent"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADER, SIZE=10, COLOR=RED, JUSTIFY=Center, $
END
```

The output is:

```
Selecting a Member and Adding a Parent

<table>
<thead>
<tr>
<th>Material class</th>
<th>Member Caption</th>
<th>Sales Volume</th>
<th>Sales Volume</th>

</tr>
<tr>
<td>Computer hardware</td>
<td></td>
<td>17,874,768.15</td>
<td>17,874,768.15</td>
</tr>
</tbody>
</table>
```
Example: Selecting a Member and Adding Children

In the following request, the SHOW option UP 0 TO DOWN 1 added to the WHEN phrase adds the children (Computer and Computer components) of the selected member (Computer hardware). Because no children of the selected member are excluded, and no higher level members are in the SHOW set, the full and visual totals are the same:

```sql
TABLE FILE ZOPT
WRITE SALES_VOLUME FROM FROLL.SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
WHEN MATERIAL_CLASS_CAPTION EQ 'Computer hardware';
SHOW UP 0 TO DOWN 1
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD "Selecting a Member and Adding Children"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

```

</tr>
</tbody>
</table>
```

SAP BW Reporting With WebFOCUS
Example: Selecting a Member and Showing All Ascendants

In the following request, the SHOW option TOP TO DOWN 0 added to the WHEN phrase adds all ascendants but no descendants of the selected member (Computer hardware). These parents now contain values for the measures rather than missing data symbols. However, the full total column for the ascendants contains the sum of all of their descendants, not just the specified Computer hardware member, while the visual total shows the total for only the Computer hardware member:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS.Caption HIERARCHY
WHEN MATERIAL_CLASS.Caption EQ 'Computer hardware';
SHOW TOP TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding All Ascendants"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8, $
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

```
Selecting a Member and Adding All Ascendants

<table>
<thead>
<tr>
<th>Material class Member Caption</th>
<th>Sales Volume</th>
<th>Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material class</td>

</tr>
<tr>
<td>Computer hardware</td>
<td>17,874,768.15</td>
<td>17,874,768.15</td>
</tr>
</tbody>
</table>
```
Example: Selecting a Member and Showing All Descendants

In the following request, the absence of a SHOW phrase is equivalent to SHOW UP 0 TO BOTTOM. The WHEN phrase selects the member Computer hardware. Because no children of the selected member are excluded and no higher level members are in the SHOW set, the full and visual totals are the same, and the ascendant levels display missing data symbols:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
WHEN MATERIAL_CLASS_CAPTION EQ 'Computer hardware';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Showing All Descendants"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

</table>
Example: Selecting a Member and Showing All Ascendants and Descendants

In the following request, the SHOW option TOP added to the WHEN phrase adds all ascendants and descendants (since TO BOTTOM is the default) of the selected member (Computer hardware). These parents are now in the SHOW set and contain values for the measures rather than missing data symbols. However, the full total column for the ascendants contains the sums of all of their descendants, not just the specified Computer hardware member, while the visual total shows the total for only the Computer hardware member:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
WHEN MATERIAL_CLASS_CAPTION EQ 'Computer hardware';
SHOW TOP
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding All Ascendants and Descendants"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8, $
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```
### Selecting a Member and Adding All Ascendants and Descendants

</tbody>
</table>
Example: **Displaying Members of a Range of Hierarchy Levels**

The following request uses a WHEN phrase on the MATERIAL_CLASS_LVLNO field to display members of levels 0 through 3 of the hierarchy. The SHOW option TO DOWN 0 eliminates printing of any descendant levels not selected by the WHEN phrase. The full and visual totals are the same because no children were excluded when calculating the visual totals:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROM.SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
WHEN MATERIAL_CLASS_LVLNO LE 3;
SHOW TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Displaying Members of a Range of Hierarchy Levels"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

![Displaying Members of a Range of Hierarchy Levels](image)

**Example: Selecting Members for Display and Screening on Member Values**

You use the WHEN phrase to select hierarchy members to display on the report. Each of the selected members is displayed in its context. The ascendants of selected members display missing data symbols. When a request is processed, the first step is to build the hierarchy and mark which nodes should be included, which should be excluded, and which are needed for context but should display missing data symbols according to the WHEN phrase.
The next stage fills the hierarchy with measure values. This stage applies WHERE criteria (which must select on the lowest level of the hierarchy or the report will be empty).

If a WHERE is specified without a WHEN, no nodes are marked as excluded, so no nodes display missing values.

The following request selects the portion of the hierarchy whose members contain the values Computer systems or Pumps. It shows the parents of these members and all levels of descendants. Note that the dimension property MATERIAL_TYPE__MEDIUM_NAME_ is displayed in the request and that only the leaf members have values for this property:

```
TABLE FILE ZOPT
WRITE MATERIAL_TYPE__MEDIUM_NAME_ AS 'MEDIUM NAME' SALES_VOLUME
   BY MATERIAL_CLASS_CAPTION HIERARCHY
   WHEN MATERIAL_CLASS_CAPTION EQ 'Computer systems' OR 'Pumps';
SHOW UP 1
ON TABLE SET PAGE NOPAGE
ON TABLE SET SCREEN PAPER
ON TABLE SET LINES 88
ON TABLE SUBHEAD
   "Selecting Hierarchy Members"
ON TABLE SET STYLE *
   TYPE=REPORT, SIZE=8,$
   TYPE=REPORT, GRID=OFF, WRAP=OFF, $
   TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

</tbody>
</table>
The following request selects the portion of the hierarchy whose members contain the values Computer systems or Pumps. It then screens on the dimension property MATERIAL_TYPE__MEDIUM_NAME_ equal to Finished product. This WHERE screening condition does not affect the portion of the hierarchy that was selected by WHEN, but it does not display or include in the totals those rows that had no data meeting the WHERE condition:

```
TABLE FILE ZOPT
WRITE MATERIAL_TYPE__MEDIUM_NAME_ AS 'MEDIUM NAME' SALES_VOLUME BY MATERIAL_CLASS.Caption HIERARCHY
WHEN MATERIAL_CLASS.Caption EQ 'Computer systems' OR 'Pumps';
SHOW UP 1
WHERE MATERIAL_TYPE__MEDIUM_NAME_ EQ 'Finished product';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting Members and Screening Data Values"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

```
Selecting Members and Screening Data Values

<table>
<thead>
<tr>
<th>Material class Member Caption</th>

</tbody>
</table>
```
**Example:** Comparing Member Selection With Data Screening

The following request selects hierarchy levels less than or equal to 3 and screens values at the lowest level of the hierarchy for captions containing Flatscreen or Harddisk. The SHOW option TO DOWN 0 prevents the display of descendants of the selected members:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS.Caption HIERARCHY
WHEN MATERIAL_CLASS_LVLNO LE 3;
SHOW TO DOWN 0
WHERE MATERIAL_CLASS.Caption CONTAINS 'Flatscreen' OR 'Harddisk';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Comparing Member Selection With Data Screening"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

### Comparing Member Selection With Data Screening

<table>
<thead>
<tr>
<th>Material class</th>
<th>Member Caption</th>
<th>Sales Volume</th>
<th>Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>35,907,899.33</td>
<td>35,907,899.33</td>
</tr>
<tr>
<td>Products</td>
<td></td>
<td>35,907,899.33</td>
<td>35,907,899.33</td>
</tr>
<tr>
<td>Computer systems</td>
<td></td>
<td>35,907,899.33</td>
<td>35,907,899.33</td>
</tr>
<tr>
<td>Computer hardware</td>
<td></td>
<td>13,865,934.28</td>
<td>13,865,934.28</td>
</tr>
<tr>
<td>Computer accessories</td>
<td></td>
<td>22,041,965.05</td>
<td>22,041,965.05</td>
</tr>
</tbody>
</table>
**Example: Using SHOW Without WHEN**

The following request does not contain a WHEN phrase, so the SHOW option DOWN TO 0 applies to the root node (as if there had been a WHEN phrase that selected only the root node). Therefore, the root level is the only one shown on the report output:

```sql
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS.Caption HIERARCHY
SHOW TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"SHOW Without WHEN"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF,$
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER,$
END

The output is:

```
SHOW Without WHEN

<table>
<thead>
<tr>
<th>Material class</th>
<th>Member Caption</th>
<th>Sales Volume</th>
<th>Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material class</td>
<td>145,209,499.79</td>
<td>145,209,499.79</td>
<td></td>
</tr>
</tbody>
</table>
```

**Example: Using SKIP-LINE**

The following request adds the BY option SKIP-LINE to the BY HIERARCHY phrase:

```sql
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS.Caption HIERARCHY
WHEN MATERIAL_CLASS.Caption EQ 'Computer hardware';
SHOW UP 2 TO DOWN 2 SKIP-LINE
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using SKIP-LINE"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF,$
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER,$
END
```
Using Sort Options Conditional on a Measure

The following request has a BY HIERARCHY command with a WHEN phrase to select members as well as a WHEN phrase to control the UNDER-LINE option. The SUBFOOT and PAGE-BREAK options are in two ON phrases that reference the same hierarchy field (all of the BY options could have been on the BY HIERARCHY phrase).

Example: Using SKIP-LINE

<table>
<thead>
<tr>
<th>Material class</th>
<th>Member Caption</th>
<th>Sales Volume</th>
<th>Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material class</td>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>Products</td>
<td>17,874,768.15</td>
<td>145,209,499.79</td>
<td></td>
</tr>
<tr>
<td>Computer systems</td>
<td>17,874,768.15</td>
<td>85,842,293.86</td>
<td></td>
</tr>
<tr>
<td>Computer hardware</td>
<td>17,874,768.15</td>
<td>17,874,768.15</td>
<td></td>
</tr>
<tr>
<td>Computer</td>
<td>1,948,298.70</td>
<td>1,948,298.70</td>
<td></td>
</tr>
<tr>
<td>Desktop computer</td>
<td>1,948,298.70</td>
<td>1,948,298.70</td>
<td></td>
</tr>
<tr>
<td>Computer components</td>
<td>15,926,469.45</td>
<td>15,926,469.45</td>
<td></td>
</tr>
<tr>
<td>RAM</td>
<td>545,330.61</td>
<td>545,330.61</td>
<td></td>
</tr>
<tr>
<td>Hard disks</td>
<td>13,865,934.28</td>
<td>13,865,934.28</td>
<td></td>
</tr>
<tr>
<td>Processors</td>
<td>1,495,035.56</td>
<td>1,495,035.56</td>
<td></td>
</tr>
<tr>
<td>Drives</td>
<td>20,169.00</td>
<td>20,169.00</td>
<td></td>
</tr>
</tbody>
</table>
Each BY option has its own WHEN phrase. Note that the WHEN phrases for the BY options use a measure field in their expressions. In this example, all of the BY options are activated when the sales volume value is zero:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
WHEN MATERIAL_CLASS_CAPTION EQ 'Computer hardware';
SHOW TOP UNDER-LINE WHEN SALES_VOLUME EQ 0;
ON MATERIAL_CLASS_CAPTION SUBFOOT
" "
"The Sum is zero"
" "
WHEN SALES_VOLUME EQ 0;
ON MATERIAL_CLASS_CAPTION PAGE-BREAK WHEN SALES_VOLUME EQ 0;
ON TABLE SUBHEAD
"Using BY Options With WHEN on a Measure"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```
63. Using the Adapter for SAP Business Intelligence Warehouse (BW)

The output is:

**Using BY Options With WHEN on a Measure**

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>Processor</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Memory</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Disk Drive</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CD-ROM</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Example:**

```
<table>
<thead>
<tr>
<th>Computer</th>
<th>MEDIA NAME</th>
<th>Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Note:** The table above shows a typical configuration list for a computer model. Each entry in the table represents a different component of the computer, along with its media name and sales volume. The table format allows for easy comparison and selection of different models based on their components and performance metrics.
Example: Using Sort Options Conditional on a Hierarchy Field

The following request has a BY HIERARCHY command with a WHEN phrase to select members. The ON phrase has a PAGE-BREAK option that is activated when MATERIAL_CLASS_CAPTION contains 'Harddisk':

```
TABLE FILE ZOPT
WRITE SALES_VOLUME FROLL.SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
WHEN MATERIAL_CLASS_CAPTION EQ 'Computer hardware';
SHOW UP 2
ON MATERIAL_CLASS_CAPTION PAGE-BREAK
WHEN MATERIAL_CLASS_CAPTION CONTAINS 'Harddisk';
ON TABLE SUBHEAD
"Using PAGE-BREAK With WHEN on a Hierarchy Field"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

Example: Using BY HIERARCHY and BY Phrases

The following request has a BY phrase for the World/Continents/Countries hierarchy and a BY HIERARCHY phrase for the Material Class hierarchy. All selected members for the Material Class hierarchy are repeated for each selected member of the World/Continents/Countries hierarchy (which is not displayed with hierarchical indentations when referenced in a BY phrase). A BY on a unique field is required. Because the captions are not unique for the World/Continents/Countries hierarchy, there is one BY on a unique field with the NOPRINT option and another BY on the caption field:

```plaintext
TABLE FILE ZOPT
WRITE SALES_VOLUME
  BY WORLD___CONTINENTS___COUNTRIES NOPRINT
  BY WORLD___CONTINENTS___COUNTRIES_CAPTION
  BY MATERIAL_CLASS_CAPTION HIERARCHY
SHOW TO DOWN 2
WHERE WORLD___CONTINENTS___COUNTRIES_CAPTION OMITS 'TEST'
  AND WORLD___CONTINENTS___COUNTRIES_LVLNO EQ 2;
WHERE TOTAL SALES_VOLUME NE 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
  "Using BY HIERARCHY and BY Phrases"
ON TABLE SET STYLE *
  TYPE=REPORT, SIZE=8,$
  TYPE=REPORT, GRID=OFF, WRAP=OFF, $
  TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```
The output is:

</tbody>
</table>
Example: **Using ON HIERARCHY Without BY HIERARCHY**

The following request has a BY phrase and an ON HIERARCHY phrase for the Material Class hierarchy. All hierarchy options and BY options are supported on the ON HIERARCHY phrase. This request also has a WHERE clause that selects rows based on the value of a hierarchy field (MATERIAL_CLASS_CAPTION). The WHERE test selects rows based on values at the leaf nodes (Harddisk is a value found on leaf nodes):

```
TABLE FILE ZOPT
WRITE SALES_VOLUME

Reference: **Hierarchical Reports With Multiple Display Commands**

In a request with more than one display command, each command must repeat all of the sort phrases from the previous command in the same order after which additional sort phrases can be added. In a hierarchical reporting request, the following rules must be followed:

- All display commands must be summation commands. PRINT is not supported in a hierarchical reporting request.
Both BY and BY HIERARCHY sort phrases can be used. As with a non-hierarchical request, all of the sort phrases must be repeated in the same order with a subsequent display command.

Only one WHEN and one SHOW phrase can be specified for each hierarchy referenced in the request. These phrases can be specified at any level of the request, but they will apply to every display command in the request.

**Example: Using Multiple Display Commands in a Hierarchical Report**

The following request has two WRITE commands. The first WRITE command has a BY HIERARCHY sort phrase for the MATERIAL CLASS hierarchy and a BY HIERARCHY phrase for the WORLD_CONTINENTS_COUNTRIES hierarchy. The second WRITE command repeats these phrases and adds a BY phrase for the SALESORG dimension:

```
TABLE FILE ZOPT
WRITE SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
WHEN MATERIAL_CLASS_CAPTION EQ 'Computer hardware'; AS 'Material Class'
SHOW TO DOWN 2

BY WORLD___CONTINENTS___COUNTRIES_CAPTION HIERARCHY
WHEN WORLD___CONTINENTS___COUNTRIES_CAPTION OMITS 'TEST'
AND WORLD___CONTINENTS___COUNTRIES_LVLNO EQ 2; AS 'Region'

WRITE SALES_VOLUME SALES_ORDER_ITEM
BY MATERIAL_CLASS_CAPTION HIERARCHY
BY WORLD___CONTINENTS___COUNTRIES_CAPTION HIERARCHY

BY SALES_ORGANIZATION_LEVEL_01 AS 'Sales Organization'
```

The BY HIERARCHY phrase for the MATERIAL CLASS hierarchy has a WHEN phrase that selects members whose caption is *Computer hardware*. The SHOW option (TO DOWN 2) displays two levels of descendants below the Computer hardware level. Ascendants of the selected members display for context, but with missing data symbols instead of values.
For the WORLD_CONTINENTS_COUNTRIES hierarchy, the selected members have level number two and do not have the characters TEST in their captions. The SHOW option displays two levels of descendants on the report output. Ascendants display for context, with missing data symbols. All selected members of the WORLD_CLASS_COUNTRIES hierarchy display for each selected member of the MATERIAL CLASS hierarchy.

The output is:

Columnar Reporting

Example:
Displaying Single Dimensions in a Slice Report
Displaying Multiple Dimensions in a Slice Report

Reference:
Valid and Invalid Slices-Cube Slicing Logic

If you run a standard TABLE or FML report against a cube, you are running what is known as a Slice report. This two-dimensional report resembles a slice of a larger multi-dimensional cube. A Slice report flattens out the multi-dimensional structure of a cube to show information from one angle.

To create a valid Slice report, you must understand the cube data structure and the logic and assumptions that the Adapter for SAP BW uses when slicing a cube.

Reference: Valid and Invalid Slices-Cube Slicing Logic

The Adapter for SAP BW has built-in logic that enables it to determine the rows and cells to extract from rollups in order to deliver Slice reports. TABLE uses the lowest level BY phrase for each dimension to determine at which rollup to locate the lookup for aggregations. It then rolls the result up from there, performing aggregations on the data as needed to ensure the consistency of the results.

If you do not specify a BY field in your TABLE request, you may receive invalid data or a message. This happens because without a BY field to determine the level of rollup at which to perform the data lookup, TABLE does not know where to source the result.

Example: Displaying Single Dimensions in a Slice Report

TABLE FILE MYCUBE
SUM STORE_COST STORE_SALES
BY COUNTRY_LEVEL_01 ON TABLE COLUMN_TOTAL
END

This report displays aggregate data sorted against one dimension in the source. The standard measures such as STORE_COST and STORE_SALES are referenced with SUM. Column totals are requested in the report.
**Example:** Displaying Multiple Dimensions in a Slice Report

```sql
TABLE FILE MYCUBE
SUM STORE_COST STORE_SALES
PRINT PROFIT
BY COUNTRY_LEVEL_01 BY STATE_PROVINCE_LEVEL BY CITY_LEVEL_01
END
```

This report displays the same data as the previous one, except that it sorts against both dimension hierarchies in the cube. The order of the sort fields follows the logical order of the dimension hierarchy.

**Reporting With Variables**

A BW query uses variables to supply values at execution time. A variable can have an Entry_Type of either Mandatory/Required or Optional. All mandatory variable values must be supplied in the TABLE or SQL request. A WHERE or IF statement in the request provides the run-time value(s). For example, if the variable COMPANY_CODE is mandatory, it will supply values for company code 430 at run time:

```sql
WHERE COMPANY_CODE_N EQ '430'
```

All variables passed to BW have a format of 124 alpha bytes. The Master File synonym breaks variables into two parts: variable_C and variable_N.

- The caption (_C) is the first 60 bytes and is an internal reference for BW.
- The name (_N) is the last 64 bytes in which the actual key value will be sent to the query.

SAP BW expects the literals in SAP VARIABLES clauses to contain only the uncompounded part of the member name. Although the Adapter for SAP BW communicates with the user in terms of member names and captions (for variables of MEMBER type), it automatically detects compounding and generates a literal based on the uncompounded part of the supplied member name. In order to obtain meaningful reports when using compounded variables the user has to be familiar with the SAP OSS Note 605208 and follow its directions. Effectively it mandates either creation of a separate variable on the compounding characteristic or a single value hard filter on it. Please see the OSS Note 605208 for further information.

In the previous example, the name (_N) supplies the variable value. You can use either the caption or the name for screening, but you must supply appropriate values for each:

```sql
company_code_n : WHERE COMPANY_CODE_N EQ 430
company_code_c : WHERE COMPANY_CODE_N EQ 'IDES USA'
```
Tip: If the associated dimension of this variable is available in the query, do not build the selection on that field, but, rather, use the name. In other words, WHERE COMPANY_CODE_LEVEL_01 EQ 430 will not populate the variable, while COMPANY_CODE_N will. Additional non-variable selections are available, but they are less efficient. The non-variable conditions are applied after the BW answer set has been extracted.

Variables cannot be displayed in a request. They should be used only for applying selection criteria. You can display the dimensions or measures with which they are associated.

You cannot display a variable as a BY field. Variables can have a selection type of single, interval, or complex.

- Single type variables must have only one value supplied in the selection condition.
- Interval variables can have a single value or a range of values.
- Complex variables have no restrictions.

To supply a range, use two WHERE statements or combine them into one statement using AND. For example, this report needs to specify two years:

```
WHERE FISCAL_YEAR_N EQ '2001'
    OR FISCAL_YEAR_N EQ '2002'
WHERE FISCAL_YEAR_N GE '2001'
WHERE FISCAL_YEAR_N LE '2002'
WHERE FISCAL_YEAR_N GE '2001'
    AND FISCAL_YEAR_N LE '2002'
WHERE FISCAL_YEAR_N IN ('2001', '2002')
WHERE FISCAL_YEAR_N FROM '2001' TO '2002'
```

Selections that use an OR connector, like the first sample above, can only test against the same field or related hierarchy. You cannot combine variable selection and non-variable selection in the same WHERE statement (screening predicate).

**Full and Partial Aggregation**

**Reference:**

- Support for Full Aggregation Mode
- Support for Partial Aggregation Mode

Cube requests are requests that reference at least one measure and possibly more than one hierarchy. Variables may also be referenced.

For cube requests, the adapter reads cells with fully or partially aggregated data from the cube and applies certain restrictions on the contents of the TABLE request to ensure consistency of reports.
There are two modes in which cube requests are processed: Full Aggregation and Partial Aggregation.

- In full aggregation mode, the adapter retrieves aggregated values from the cube exactly as they will be displayed on the report.
- In partial aggregation mode the Adapter retrieves partially aggregated data which is then further aggregated by WebFOCUS.

Full aggregation mode is more efficient because no aggregation is needed beyond what is already stored in the cube.

**Reference:** Support for Full Aggregation Mode

The following table describes support for full aggregation mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Dimension Properties</th>
<th>Measures</th>
<th>Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>WRITE/ SUM/ADD</td>
<td>Supported, converted to FST.</td>
<td>Supported, converted to an operation that matches the measure aggregator.</td>
<td>Not supported.</td>
</tr>
<tr>
<td>COMPUTE</td>
<td>Supported.</td>
<td>Supported.</td>
<td>Not supported.</td>
</tr>
<tr>
<td>PRINT</td>
<td>Supported.</td>
<td>Supported for compatibility. Not supported with BY HIERARCHY.</td>
<td>Not supported.</td>

<tr>
<td>WHERE TOTAL</td>
<td>Supported.</td>
<td>Supported.</td>
<td>Not supported.</td>
</tr>
<tr>
<td>WHERE</td>
<td>Supported.</td>
<td>Not supported.</td>
<td>Required for mandatory variables; must provide required restriction for its variable selection type. Restricted to a group of fields that represent a single variable.</td>
</tr>
<tr>
<td>WHEN</td>
<td>Supported.</td>
<td>Not supported.</td>
<td>Not supported.</td>
</tr>
</tbody>
</table>
### Support for Partial Aggregation Mode

In partial aggregation mode, there are additional restrictions on the use of measures. Note that in requests with multiple display commands, the partial aggregation restrictions apply to all display commands except for the ones associated with the lowest BY phrase:

- **Additive aggregators** (those that can be further aggregated from partial totals such as `SUM.`, `CNT.`, `MAX.`, and `MIN.`) are supported as long as they match the measure aggregator.

- **Non-additive aggregators** (such as `AVE.`) are not supported.

The following factors turn on partial aggregation mode:

- Multiple display commands.

- Parent/Child hierarchies: Visual totals or Full totals with a WHERE on the hierarchy.

- Level hierarchies: Not all levels of a hierarchy that are referenced in the request have BY phrases.

- All hierarchies: The hierarchy is referenced only in a WHERE clause that selects more than one member.
Support for Time Dependent Hierarchies

Example:

Time Dependent Hierarchies in a Master File
Reporting Against Time Dependent Hierarchies

The contents of a hierarchy may change over time. As changes occur, multiple versions of the hierarchy for different time periods accumulate. Results of a report from the cube depend on which of the hierarchy versions is selected at report time.

A cube can be created that has multiple time-dependent hierarchies, each having different versions for different time periods.

When you create a report against such a cube, you cannot arbitrarily choose the versions of time-dependent hierarchies because only certain combinations of versions make business sense. The way to choose versions of time-dependent hierarchies is by indicating what is called the key date. When you specify a key date you are saying you want to see the contents of the cube as of that effective date. The BW system automatically chooses the proper combination of versions of the time-dependent hierarchies valid for this key date.

Time-dependent hierarchies sometimes may also have multiple concurrent versions of the same hierarchy. The number of these versions changes with time and is reflected in the cube metadata. Depending on the key date, the BW system exposes a varying number of these concurrent versions, each as a separate distinctly named hierarchy. Thus, not only the contents of a hierarchy can change with time, but also the number of its concurrent (simultaneously existing) versions can change.

When you create a synonym against a cube with time dependent hierarchies, you can specify a key date and produce a Master File that contains all versions of the hierarchies (time dependent and not) that existed for the time period associated with the specified key date. In the synonym, different concurrent versions of the same hierarchy have different field names that let you distinguish between the versions. Specifying the key date at the time of synonym creation makes sense mostly in the presence of a time-dependent hierarchy that has or has had multiple concurrent versions. The key date should be specified for a period of time when the hierarchy had the maximum number of concurrent versions.

If you do not specify a key date when creating a synonym, the current date is used as the key date. If all the time-dependent hierarchies in the cube have only time-changing contents but do not have varying numbers of concurrent versions, specification of the key date at create synonym time makes sense only when simultaneously requesting member sampling. Otherwise, the resulting synonym will be identical no matter what key date has been specified.
When you report against a time-dependent hierarchy, you use the ENGINE BWBAPI SET KEY_DATE command to set a key date for subsequent TABLE requests. If you do not specify the key date, the current date is used as the key date. The contents of all time-dependent hierarchies in the cube will be exposed in the report as they were at the specified key date. To report against a specific concurrent version of the hierarchy, reference the field names associated with that version of the hierarchy in your request. This has to be coordinated with the key date that you specify. If you do not specify a correct key date (the one within the time period associated with the specified concurrent version of the hierarchy) your report will fail with an error message indicating absence of the specified hierarchy.

**Example:**  
**Time Dependent Hierarchies in a Master File**

The following portion of a Master File was produced using the key date 20081031 against the $0SD_C01 cube. Time-dependent hierarchies are defined for the 0MATERIAL dimension. The concurrent versions of the time dependent hierarchy are indicated in bold:

```
DIMENSION=[0MATERIAL], CAPTION='Material', $  
  HIERARCHY=[0MATERIAL], CAPTION='Material', HRY_DIMENSION=[0MATERIAL],  
  HRY_STRUCTURE=STANDARD, $  
  HIERARCHY=[0MATERIAL] 001, CAPTION='Material class', HRY_DIMENSION=[0MATERIAL], HRY_STRUCTURE=RECURSIVE, $  
  HIERARCHY=[0MATERIAL] MAT_CLASS_TD V1], CAPTION='Material Class Time Dep', HRY_DIMENSION=[0MATERIAL], HRY_STRUCTURE=RECURSIVE, $  
  HIERARCHY=[0MATERIAL] MAT_CLASS_TD V2], CAPTION='Material Class Time Dep', HRY_DIMENSION=[0MATERIAL], HRY_STRUCTURE=RECURSIVE, $  
  HIERARCHY=[0MATERIAL] PRDHA], CAPTION='Product Hierarchy for material MARA', HRY_DIMENSION=[0MATERIAL],  
  HRY_STRUCTURE=RECURSIVE, $  
  HIERARCHY=[0MATERIAL] RCV], CAPTION='Retail category view', HRY_DIMENSION=[0MATERIAL], HRY_STRUCTURE=RECURSIVE, $  
```

The following portion of the Master File shows the fields listed for the two concurrent versions of the time dependent hierarchy. Note that the fields listed for the first version have the characters TIME_DEP in their names, and the fields listed for the second version have the characters TIME_DEP1 in their names:

**Fields for Version 1 of the time dependent hierarchy:**

```
FIELDNAME=MATERIAL_CLASS_TIME_DEP, USAGE=A143, ACTUAL=A143,  
MISSING=ON,  
TITLE='Material Class Time Dep Member Unique Name',  
WITHIN='*[0MATERIAL MAT_CLASS_TD V1]',  
PROPERTY=UID, $  
```
FIELDNAME=MATERIAL_CLASS_TIME_DEP_NAME, USAGE=A64, ACTUAL=A64, MISSING=ON,
   TITLE='Material Class Time Dep Member Name',
   REFERENCE=MATERIAL_CLASS_TIME_DEP, PROPERTY=NAME, $

FIELDNAME=MATERIAL_CLASS_TIME_DEP_LVLNO, USAGE=I2L, ACTUAL=I4, MISSING=ON,
   TITLE='Material Class Time Dep Member Level Number',

FIELDNAME=MATERIAL_CLASS_TIME_DEP_CAPTION, USAGE=A60, ACTUAL=A60, MISSING=ON,
   TITLE='Material Class Time Dep Member Caption',
   REFERENCE=MATERIAL_CLASS_TIME_DEP, PROPERTY=CAPTION, $
Fields for Version 2 of the time dependent hierarchy:

```plaintext
FIELDNAME=MATERIAL_CLASS_TIME_DEP1, USAGE=A143, ACTUAL=A143,
   MISSING=ON,
   TITLE='Material Class Time Dep Member Unique Name',
   WITHIN='*[OMATERIAL                MAT_CLASS_TD               V2]',
   PROPERTY=UID, $
FIELDNAME=MATERIAL_CLASS_TIME_DEP1_NAME, USAGE=A64, ACTUAL=A64,
   MISSING=ON,
   TITLE='Material Class Time Dep Member Name',
   REFERENCE=MATERIAL_CLASS_TIME_DEP1, PROPERTY=NAME, $
FIELDNAME=MATERIAL_CLASS_TIME_DEP1_LVLNO, USAGE=I2L, ACTUAL=I4,
   MISSING=ON,
   TITLE='Material Class Time Dep Member Level Number',
   REFERENCE=MATERIAL_CLASS_TIME_DEP1, PROPERTY=LEVEL_NUMBER, $
FIELDNAME=MATERIAL_CLASS_TIME_DEP1_PARENT, USAGE=A143, ACTUAL=A143,
   MISSING=ON,
   TITLE='Material Class Time Dep Parent Unique Name',
   REFERENCE=MATERIAL_CLASS_TIME_DEP1, PROPERTY=PARENT_OF, $
FIELDNAME=MATERIAL_CLASS_TIME_DEP1_PARENT_LVLNO, USAGE=I2L,ACTUAL=I4,
   MISSING=ON,
   TITLE='Material Class Time Dep Parent Level',
   REFERENCE=MATERIAL_CLASS_TIME_DEP1, PROPERTY=PARENT_LEVEL_NUMBER, $
FIELDNAME=MATERIAL_CLASS_TIME_DEP1_CHILDREN_CARD, USAGE=I9,ACTUAL=I4,
   MISSING=ON,
   TITLE='Material Class Time Dep Member Children Cardinality',
   REFERENCE=MATERIAL_CLASS_TIME_DEP1, PROPERTY=CHILDREN_CARDINALITY, $
FIELDNAME=MATERIAL_CLASS_TIME_DEP1_CAPTION, USAGE=A60, ACTUAL=A60,
   MISSING=ON,
   TITLE='Material Class Time Dep Member Caption',
   REFERENCE=MATERIAL_CLASS_TIME_DEP1, PROPERTY=CAPTION, $
```

Example: Reporting Against Time Dependent Hierarchies

The following request reports against a synonym named TIMEDEP that was created using the key date 20081031. It lists the net value of sales volume for the first version of the time dependent OMATERIAL hierarchy. The request displays three levels of the hierarchy and only non-empty cells:

```plaintext
ENGINE BWBAPI SET KEY_DATE 20081031
TABLE FILE TIMEDEP
SUM NET_VALUE_OF_SALES_VOLUME
BY MATERIAL_CLASS_TIME_DEP1_CAPTION HIERARCHY
SHOW TO DOWN 3
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
END
```
The following request uses the second version of the time dependent hierarchy:

```sql
ENGINE BWBAPI SET KEY_DATE 20081031
TABLE FILE TIMEDEP
SUM NET_VALUE_OF_SALES_VOLUME
BY MATERIAL_CLASS_TIME_DEP1_CAPTION HIERARCHY
SHOW TO DOWN 3
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
END
```

The output is:

<table>
<thead>
<tr>
<th>Material Class Time Dep Member Caption</th>
<th>Net Value of Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESSORIES</td>
<td>31,926,127.92</td>
</tr>
<tr>
<td>Parts</td>
<td>31,926,127.92</td>
</tr>
<tr>
<td>Deluxe Headlight</td>
<td>1,770,180.46</td>
</tr>
<tr>
<td>Deluxe Taillight</td>
<td>566,089.48</td>
</tr>
<tr>
<td>SunFun / 1200 cm3</td>
<td>29,589,857.98</td>
</tr>
</tbody>
</table>

The following request uses the second version of the time dependent hierarchy:

```sql
ENGINE BWBAPI SET KEY_DATE 20081031
TABLE FILE TIMEDEP
SUM NET_VALUE_OF_SALES_VOLUME
BY MATERIAL_CLASS_TIME_DEP1_CAPTION HIERARCHY
SHOW TO DOWN 3
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
END
```

The output is:

<table>
<thead>
<tr>
<th>Material Class Time Dep Member Caption</th>
<th>Net Value of Sales Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESSORIES</td>
<td>1,770,180.46</td>
</tr>
<tr>
<td>Parts</td>
<td>1,770,180.46</td>
</tr>
<tr>
<td>Deluxe Headlight</td>
<td>1,770,180.46</td>
</tr>
</tbody>
</table>

Following is the same request against the version of the hierarchy that is not time dependent. The results will be the same for any key date when using this version of the hierarchy:

```sql
TABLE FILE TIMEDEP
SUM NET_VALUE_OF_SALES_VOLUME
BY MATERIAL_CLASS_CAPTION HIERARCHY
SHOW TO DOWN 3
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
END
```
Reversing the Sign When Displaying a Measure

How to:
Display a Measure With Reversed Signs

Example:
Displaying a Measure With Reversed Signs

In a BEX query, one of the options available for a measure is to display its values with reversed plus and minus signs. If you know that the BEX query has specified that a measure should be displayed with reversed signs, you can use the DMC to create a synonym that enables display of that measure on WebFOCUS reports with reversed signs. This is done by adding the REVERSE_SIGN=ON attribute to the field declaration for that measure.

The signs are reversed whenever this attribute is present, whether the BEX query specified a reverse sign or not, so you must know the data and the query definition before applying this attribute. This attribute has no effect on the stored values of the measure, just their display.

Syntax: How to Display a Measure With Reversed Signs

Add the following attribute to the FIELD declaration for the measure to be displayed with reverse signs:

REVERSE_SIGN=ON
Example: Displaying a Measure With Reversed Signs

In the following partial listing of the ZMINUS synonym, the measure CM_1 has the
REVERSE_SIGN=ON attribute. This attribute has been added because the BEX query specifies
reversed signs for measure CM_1:

FILENAME=ZMINUS, SUFFIX=BWBAPI, $
SEGMENT=ZMINUS, SEGTYPE=S0, $
$ MEASURES FOR CUBE 0SD_C01/ZMINUS
  FIELDDNAME=CM_1, ALIAS=4KN324NNXDL1055YDEO17L0L8, USAGE=D18.2,
    ACTUAL=D8, MISSING=ON, TITLE='CM 1',
      REFERENCE=SUM, PROPERTY=MEASURE, REVERSE_SIGN=ON, $
  FIELDDNAME=COST_OF_SALES____, ALIAS=4KN324VCGC6Q1RPEJ8QDHMZB0,
    USAGE=D18.5, ACTUAL=D8, MISSING=ON, TITLE='Cost of Sales (%)',
      REFERENCE=UNKNOWN, PROPERTY=MEASURE, $
DIMENSION=[0MATERIAL], CAPTION='Material', $
HIERARCHY=[0MATERIAL], CAPTION='Material', HRY_DIMENSION=[0MATERIAL],
  HRY_STRUCTURE=STANDARD, $
HIERARCHY=[0MATERIAL 001], CAPTION='Material class',
  HRY_DIMENSION=[0MATERIAL], HRY_STRUCTURE=RECURSIVE, $

The following request against the ZMINUS synonym prints the measures CM_1 and
Cost_of_Sales:

TABLE FILE ZMINUS
PRINT CM_1 COST_OF_SALES
BY MATERIAL_NAME
END
The partial output follows. The measure CM_1 is displayed with reverse signs:

<table>
<thead>
<tr>
<th>Material Member Name</th>
<th>CM_1</th>
<th>Cost of Sales (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>100-400</td>
<td>0.00</td>
<td></td>
</tr>
<tr>
<td>1400-100</td>
<td>486,395.92</td>
<td>72.52281</td>
</tr>
<tr>
<td>1400-200</td>
<td>177,820.37</td>
<td>68.58794</td>

**Reporting Rules**

**Reference:**

- Display Command and Prefix Operator Support
- Reporting Rules for All Hierarchies
- Reporting Rules for Parent/Child Hierarchies

The reporting rules and features vary depending on the types of hierarchies defined in the synonym. These factors are summarized in the following sections.
Display Command and Prefix Operator Support

When BY HIERARCHY is not used in the request, the display command can be PRINT, even for aggregated data. It is internally converted to the appropriate command.

**Note:** To emphasize that the summary values are already in the cube and do not necessarily require any additional aggregation, the examples use the WRITE command, which is a synonym for SUM.

The measure operation is also automatically supplied internally. You do not have to specify a prefix operator in the request. However, if you do specify a prefix operator, it should match the measure aggregator.

For example, assume there is a measure called ASALES and another measure called SALES, where SALES is a simple sum and ASALES is an average. A request referencing SALES and ASALES can use the following display command:

```
WRITE SALES ASALES
```

The operation for the ASALES measure will automatically be converted internally to AVE.ASALES.

You can also specify the summarizing operation in the command:

```
WRITE SALES AVE.ASALES
```

In the synonym, the REFERENCE= attribute specifies the measure aggregator. For example, REFERENCE=SUM.

If you do specify prefix operators in the request, you can prevent the adapter from checking whether your operation matches the measure aggregator by issuing the following command:

```
ENGINE BWBABI SET CHECKAGGR OFF
```

Reporting Rules for All Hierarchies

**Variables.** SAP BW expects a query to contain values for variables. Values for all mandatory variables must be supplied. The method for specifying variable values is to include a WHERE or IF phrase in the TABLE request.

For example, the following WHERE phrase supplies the value 430 for the COMPANY_CODE variable:

```
WHERE COMPANY_CODE_N EQ '430'
```

**BY.** Lexicographic sort is available on any of the member properties as well as expressions (DEFINEs) based on properties, but the request must include a sort (possibly with the NOPRINT option) on a property that is guaranteed to uniquely identify a hierarchy member, either PROPERTY=UID or PROPERTY=NAME. BY HIERARCHY automatically adds a BY one of these properties. In a report referencing a level hierarchy, the request must specify one.
**Hierarchies.** Only one hierarchy from the same dimension can be represented on the report.

**Cardinality.** Cardinality is the number of members in a dimension, hierarchy, or hierarchy level. Because SAP BW is a multi-dimensional database, the volume of the report may grow as a product of cardinalities of the referenced dimensions unless you include a WHERE test to restrict the number of returned dimension members.

**Measures.** Filtering on totals is done using WHERE TOTAL tests. Calculations on totals are done using COMPUTE.

**Screening.** Screening on member properties is available with and without sorting.

**Reference:** Reporting Rules for Parent/Child Hierarchies

**BY HIERARCHY.** Requires the command SUM, WRITE, or ADD. PRINT is not supported.

**Hierarchical Context.** The set of members selected for the report using a WHEN test is augmented so that every member of the hierarchy is shown within its hierarchical context. The displayed subtree of hierarchy members is a contiguous tree whose root is the root of the whole hierarchy. The added context members are shown without totals.

**Report Compression.** By default, hierarchy members with no fact data do not participate in the report. Hierarchy members for which no data passes screening do not participate in the report. In a multi-hierarchy report, the inner hierarchies are not shown for those members of outer hierarchies that appear on the report output only to show the context of selected members.

**Full and Visual Totals.** Visual totals for each node are composed from the totals of its hierarchical children shown on the same report. These are compatible with the totals shown for the same members in a multi-verb level-wise report. Visual totals are the default. The report can specify full totals by specifying the prefix operator FROLL on a measure field. Full totals are accumulated for each displayed hierarchy member individually. These are compatible with the totals shown for the same members in a non-hierarchical report on a parent-child hierarchy.

**General Tips for Reporting**

When creating a report request:

- PRINT and SUM can be used interchangeably when using level hierarchies.
  
  When reporting from Operational Data Store (ODS) or InfoSet Queries (ODS joins), depending on the summarization setting of the key fields, you may use the PRINT verb. When using PRINT against ODS objects, the BY fields (not to be confused with Key Figures Fields) determine the summarization level of unique values.

- To maximize reporting efficiency, always sort in the same direction as the hierarchy for the cube.
For example, if the hierarchy for a dimension is

Country > State_Province > City

sorting by City first, then State_Province results in an inefficient request. Also, because of the hierarchical structure of OLAP, you retrieve only one BY field for each SUM or PRINT field in the report.

**SAP BW Support for Hierarchies**

**Reference:** Creating Dynamic Hierarchies

In SAP BW release 3.0A and earlier, one characteristic of the query can be expanded in a hierarchical display.

**Reference:** Creating Dynamic Hierarchies

The Adapter for SAP BW generates each level of a hierarchy with a field name corresponding to that level. For a dimension called Business Number and a hierarchy named States, level 1 will be States and level 2 will be the Business Number. You can create a report referencing all the fields of a hierarchy at once, or create it as an OLAP trigger report, referencing the top level of the hierarchy and enabling interactive drill down.

In SAP BW 3.0B and higher, multiple characteristics of the query can be expanded in a hierarchical display.

**Creating Dynamic Dimensions**

**Example:** Creating a Dimension

SAP BW, you can:

- Create dynamic dimensions by using the Create New Field (Define) function.
- Use hierarchy levels and dimensions that are not contained in the query cube, but are defined or calculated at run time.
**Example: Creating a Dimension**

The following request creates a dimension called Daily Sales, which concatenates the company name, the current date (picked up from an the &DATE variable), and the Sales figures for that date.

```sql
DEFINE Daily Sales/A124= company|&date|'Sales'
END

TABLE FILE MYQUERY
SUM Retail_Amount
BY Daily Sales
END

The output is:

<table>
<thead>
<tr>
<th>Daily Sales</th>
<th>Retail_Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACME 11/15/2002</td>
<td>10,000</td>
</tr>
<tr>
<td>SMCE 11/15/2002</td>
<td>15,000</td>
</tr>
</tbody>
</table>

**Managing SAP BW Metadata**

In this section:

- Creating Synonyms
- Mapping Metadata
- Variable Types

SAP BW field names are generated from the Level Caption loaded in BW Master Data and obtained from the BW Query Cube. These captions provide friendly (person-readable) field names.
Note:

- **To report against an InfoProvider**, you must generate an SAP BEx Query and release it for OLAP before you can create a synonym. You will complete those tasks using the SAP Business Explorer, a tool that creates the SAP BW queries you will reference in your report requests. If you have not completed those tasks, see *Creating BEx Queries* on page 2079, then return to generating metadata.

- In order to create a synonym, you need permission on the function group SU_USER.

- **Accessing SAP BW Master Data tables.** Many organizations require analysis of Master Data in conjunction with Transactional Data in SAP BW:
  
  - Transactional Data changes frequently (for example, account data, sales and purchase orders, and inventory). This data is stored in InfoCubes and is directly accessible through the Adapter for SAP BW, where it is available for up-to-the-minute analysis.
  
  - Master Data remains unchanged over a long period of time and is always needed in the same way (for example, access authorizations, standard printer information, and organization structures). However, this data is stored in SAP BW Master Data Tables that may not initially be accessible in the cube-based SAP BW environment.

Since this complex analysis is predicated upon access to the Master Data, you must be able to make the Master Data tables accessible within the SAP BW environment. You can accomplish this by completing a simple configuration procedure using the table-based Adapter for SAP ECC.

### Creating Synonyms

**How to:**

Create a Synonym

**Example:**

Code Pages and Multilanguage Synonyms

**Reference:**

Synonym Creation Parameters for SAP BW

Multilanguage Titles and Descriptions

Managing Synonyms

Synonyms define unique names (or aliases) for each SAP BW table or view that is accessible from a server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.
Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

**Note:** In order to create a synonym, you need permission on the function group SU_USER.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   
   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   
   The *Select adapter to configure or Select connection to create synonym* pane opens.

3. Click a connection for the configured adapter.
   
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.
   
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.
Reference: Synonym Creation Parameters for SAP BW

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

Filter by Catalog and Cube

To display all available queries, leave the Filter by Catalog and Cube check box blank.

To filter by Catalog name, Cube name, or Description, click the check box. Three input boxes are displayed. Enter the name of the Catalog (InfoCube), Cube (Query Cube), or description in the appropriate box. You can use the wildcard character (*) as needed. For example:

0CCA*

When issuing a request against a query cube, the adapter creates the cube name from these components: the full catalog name, followed by a forward slash (/), followed by the query cube name.

If you enter a description, it must be a contiguous portion of the SAP BW description from the InfoCube or Query Cube.

Multilanguage

A synonym can be created using one or more languages. If you choose multiple languages, each selected language can have its own title and description attributes. For details on multilanguage titles and descriptions, see Multilanguage Titles and Descriptions on page 2158.

1. Click the Multilanguage check box to select languages in addition to the default logon language (the value of the SET LANGUAGE command at server startup). The list of available languages is displayed. (The default language is not on the list.)

2. You may select one or more additional languages.

For SAP BW, you must be authorized for each language you wish to access. Your userid and password are stored in the sapserv.cfg. The languages are retrieved from your selections on this list.

Note, however, that for the your language selections to be implemented, the selected languages must be installed. Also NLS must be enabled and your language selections must be consistent with your code page settings in the NLS Configuration Wizard. To access this wizard from the Web Console menu bar, select Workspace, Configuration. In the navigation pane, expand the General folder and click NLS. For related information, see Code Pages and Multilanguage Synonyms on page 2158.
In addition, a Field Names option is displayed (see next item on chart for details).

**Field Names**

If you have selected Multilanguage synonyms, you can choose to use *Technical* or *Language*-based field names:

- **Technical** names are based on the global ID of the SAP BW object.
- **Language** names use the caption (description) of the BW object. Language-based name is the default setting.

If you choose Language-based, a Field Name case option becomes available (see next item on chart for details).

**Field Name Case**

For Language-based field names, choose Uppercase or Mixed-case:

- **Uppercase** displays all field names in the Master File component of the synonym in uppercase characters.
- **Mixed-case** displays field names in the Master File in the same case that is used by SAP BW. Mixed-case is the default setting.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Hierarchy Type**

Select the type of hierarchy you want to create in the synonyms by choosing one of the following options from the *Hierarchy type* drop-down list:

- **Optimized.** This option creates synonyms in which hierarchies are represented as parent/child relationships except for the flat hierarchy. The flat hierarchy (the list of all leaf nodes whose parent is the root node) is represented as a level hierarchy with two fields, one with a field name of the form `hierarchy_name_LEVEL_01` (containing the member’s caption) and one with a field name of the form `hierarchy_name_NAME` (containing the member’s name).

- **Level.** This option creates separate fields for each hierarchy level as in prior releases.
**Note:** Existing synonyms from prior releases of the adapter may need to be migrated before you can use them in a request. To migrate a synonym, click its name on the metadata page and then click the *Migrate* option on the context menu.

**Member Sampling**

Check this box if you want the adapter to select all members of a hierarchy level to determine the optimum length for the field, and also the cardinality.

**Note:** Depending on the data volume, this may take a long time. If synonym creation takes too long, you may wish to turn the member sampling off.

When this box is unchecked, all field lengths for the hierarchy levels are set to alphanumeric 60, and the cardinality information will be missing.

**Structured Dimensions**

Structures consist of a group of characteristics and/or key figures. They can be saved and reused in other queries. You can represent SAP BW structures as dimensions or create a cartesian product of the fields in the structures. To include structures as dimensions in the synonym, check this box.

If you do not check this box, the created Master File includes fields representing the cartesian product of all fields in the structures. All of these fields are placed under the MEASURES section of the Master File and treated as separate key figures.

**Key Date**

 Produces a Master File that contains all versions of the hierarchies (time dependent and not) that existed for the time period associated with the specified key date. Specifying the key date at the time of synonym creation makes sense mostly in the presence of a time-dependent hierarchy that has or has had multiple concurrent versions. The key date should be specified for a period of time when the hierarchy had the maximum number of concurrent versions.

If no key date is specified, the current date is used.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
Select synonyms to generate

Click the radio button next to the name of each cube for which you want to create a synonym. To create synonyms for all cubes on the list, click the radio button above the list of cubes. The Default Synonym Name column specifies the synonym name that will be generated by default if you select that cube. To specify non-default names for the generated synonyms, overtype the default names.

To delete measures, dimensions, or hierarchies from the synonym, use the Data Management Console after the synonym has been created.

Reference: Multilanguage Titles and Descriptions

When you create a Multilanguage synonym, title and/or description attributes for each selected language are added to the synonym. For example, if you choose French, the synonym will contain additional TITLE and DESC attributes of the following form:

```
TITLE_FR='french title'
DESC_FR='french description'
```

The default logon language generates titles and descriptions using the TITLE and DESCRIPTION attributes.

- If you set the LANGUAGE parameter to a language for which you generated additional title and description attributes, titles and descriptions are generated with the TITLE_Ln and DESC_Ln attributes (Ln being the two character ISO code; for example, EN, DE, JA).

- If you set the LANGUAGE parameter to a language for which you did not generate additional titles or descriptions, the TITLE and DESCRIPTION attributes are used to generate titles and descriptions.

In order to make field names in the synonym language independent, they are created based on the field’s unique name (these names are called technical names). In synonyms created using only the default language, field names are created based on the field caption.

Example: Code Pages and Multilanguage Synonyms

The languages you wish to select for multilanguage synonyms determine which code page you should configure. For example, ISO 8859-1 can accommodate most Western European languages. Therefore, using this code page, you can request English, German, French, and Spanish.

The Unicode UTF-8 code page (65001) supports all languages and can therefore be used with any combination of languages. However, the UTF-8 character encoding scheme uses three bytes (in ASCII environments) or 4 bytes (in EDCDIC environments) to represent characters, increasing the storage needed for character data.
Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
</tbody>
</table>
| Data Profiling           | Data Profiling provides the data characteristics for synonym columns.  
|                          | Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.  
<p>|                          | Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.                      |
| Refresh Synonym (if applicable) | Regenerates the synonym. Use this option if the underlying object has been altered.                                                        |</p>
<table>
<thead>
<tr>
<th><strong>Option</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>
Mapping Metadata

Example:
Mapping Illustrations
Dimension: OMATERIAL

Reference:
Mapping BW InfoProviders to OLE/DB Cubes
Syntax Conventions for Master Files

OLAP (OLE DB standard) uses the following terms for row sets: Hierarchies, Levels, Measures, Members, and Dimension Properties. The corresponding terms are mapped in BW and the Adapter for SAP BW.

It is a good practice to regenerate the adapter metadata whenever data is loaded into the cube. Regeneration keeps data up-to-date and enables the adapter to accurately record the extent to which each dimension hierarchy expands.

Reference: Mapping BW InfoProviders to OLE/DB Cubes

Business Information Warehouse (BW) InfoProviders are similar to OLE/DB cubes. Both are the central metadata objects and containers for data used for reporting. InfoProviders contain two types of data: Key Figures and characteristics. For related information, see Creating BEx Queries on page 2079. For examples of these mappings, see Mapping Illustrations on page 2162.

<table>
<thead>
<tr>
<th>OLAP</th>
<th>BW</th>
<th>FOCUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cube</td>
<td>Query</td>
<td>Master File.</td>
</tr>
<tr>

<td>Characteristic</td>
<td>Internal use appears as comment in Master File (see above).</td>
</tr>
<tr>
<td>Hierarchy</td>
<td>Hierarchy</td>
<td>Dimension (An Adapter for SAP BW Dimension is a group of fields connected by means of the WITHIN keyword. The WITHIN keyword relates inner values to outer values for summary purposes.</td>
</tr>
<tr>
<td>Level</td>
<td>Level</td>
<td>Field (the WITHIN keyword points to the parent field).</td>
</tr>
<tr>
<td>Member</td>
<td>Characteristic Value</td>
<td>Field values.</td>
</tr>
<tr>
<td><strong>OLAP</strong></td>
<td><strong>BW</strong></td>
<td><strong>FOCUS</strong></td>
</tr>
<tr>
<td>----------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Dimension Property (including special property Key)</td>
<td>Attribute</td>
<td>Field (only printable when the reference Dimension Hierarchy is used as a BY field).</td>
</tr>
<tr>
<td>No OLAP mapping</td>
<td>SAP BW variable</td>
<td>Field (specially mapped in a Master File) that takes optional or required input.</td>
</tr>
<tr>
<td>Measure</td>
<td>Key Figure (Measure)</td>
<td>Numeric fields upon which FOCUS verbs (PRINT/SUM) can perform operations.</td>
</tr>
</tbody>
</table>

**Example:  Mapping Illustrations**

The following lines of syntax illustrate the makeup of the Adapter for SAP BW metadata. Each is listed with its corresponding definition:

```plaintext
FILENAME=WAREHOUSE, SUFFIX=BWBAPI,$
```

This denotes the cube descriptor. The `FILENAME=value` is generated from the query cube name.

```plaintext
SEGNAME=WAREHOUSE, SEGTYPE=S0,$
```

This is the segment name (used internally in FOCUS only). The `SEGNAME=value` is generated in the same way as `FILENAME=value`.

```plaintext
$ DIMENSION -MEASURES-
```

This is the beginning of the measures section of the Master File. The Fact Table is logically a dimension and is displayed accordingly in the Master File.

```plaintext
$ CARDINALITY=n
```

The cardinality of a dimension defines how many members can be retrieved for a report. If the Cardinality of a dimension is high, you should consider a WHERE test to restrict the returned values.

```plaintext
FIELD=STORE_INVOICE, ALIAS='STORE INVOICE', USAGE=D10.2, ACTUAL=D8.2, MISSING=OFF,$
```

This describes the measure. The first section in the Master File defines the fields that comprise the Fact Table for your cube.
$ DIMENSION: dimension_name

This is the Dimension section comment. The Adapter for SAP BW synonym logic puts
dimension names in comments before descriptions of the corresponding hierarchies
and increases the readability of the Master File. All columns that follow a dimension
comment are members of the dimension.

**Note:** Multiple hierarchies for the same dimension display as separate dimension entries.

**FIELD=PRODUCT_FAMILY, ALIAS='PRODUCT FAMILY', WITHIN= *PRODUCT, USAGE=A20,
ACTUAL=A20, MISSING=OFF,$

This is the top level of a dimension hierarchy. Each subsequent level of the hierarchy
will have a corresponding field name. Each level of the hierarchy has a following comment
line with the level unique cardinality (count of members for the level).

**Note:** The WITHIN=value cannot exceed 66 characters. If the hierarchy unique name is
longer than 65 characters (plus 1 character for *), Create Synonym generates a message.
Although OLAP supports summary levels (the root level in the hierarchy), these are not
displayed in the Master File.

**FIELD=STORE_MANAGER, ALIAS='STORE MANAGER', USAGE=A20, ACTUAL=A20,
MISSING=ON,$

This describes the Dimension property. Any fields listed in a dimension section of the
Master File that do not have an assigned hierarchy (for example, no WITHIN), represent
dimension properties. In this example, the property stores the manager name for the
store in the rollup.

**Reference:** Syntax Conventions for Master Files

The following conventions must be followed in a Master File that is used with SAP BW:

- **JOIN Restriction.** Joins are not supported in convention with BW syntax. However, you
  produce the same results using MATCH FILE.

- **Quotes are required.** Any field or hierarchy name containing blanks must be enclosed
  in single quotation marks.

- **Hierarchy levels.** Hierarchy levels do not have clearly defined data types. As a result,
  the levels are always represented as alpha.

- **Special Property - Key.** BW dimensions have a default hierarchy noted by the name of
  the dimension appended with level_01. These default hierarchy fields have a special
  property called a Key that contains the BW internal reference code for the field. A Key
  may be printed for only the default hierarchy and may be used only when it is referenced.
  A Key field may also be used in WHERE or DEFINE statements, providing the dimension
  field is referenced. In the synonym, the field name for this field has the suffix _NAME.
  For related information, see Reporting Rules for All Hierarchies on page 2149.
Example: **Dimension: 0MATERIAL**

The following example shows what can be expected when selecting the fields in a report. It is important to remember that two fields are returned for the same data value.

Field: 0MATERIAL_LEVEL01
Field: 0MATERIAL_NAME

as displayed in a report:

<table>
<thead>
<tr>
<th>0MATERIAL_LEVEL_01</th>
<th>0MATERIAL_NAME</th>
<th>TOTAL_SALES</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fitdrink 2000(CAN)</td>
<td>R100032</td>
<td>$1000.00</td>
</tr>
</tbody>
</table>

Both fields represent the same characteristic value.

0MATERIAL_LEVEL_01 is the dimension level containing the captions for all members of the dimension.

0MATERIAL_NAME contains the SAP BW technical name for the members of the dimension.

**Variable Types**

SAP BW supports four types of variables:

- **Members.** Can be displayed in a separate TABLE request. When used in a TABLE query, a search criterion must be supplied if the variable type is mandatory (and there is no default value). The search criterion must render a set of variable values that correspond to the variable, which may be single value, interval, or complex (for complex there is no restriction on combinations). Each search predicate (an AND logical expression) can reference only one variable and no other cube elements.

- **Nodes.** Can be displayed in a separate TABLE request. Node type variables have a single value selection type.

- **Hierarchies.** Can be displayed in a separate TABLE request. Hierarchy type variables have a single value selection type.

- **Numeric.** Cannot be displayed.

For related information, see *Reporting With Variables* on page 2136.
# Customization Settings

## How to:

- Specify Empty Report Cell Settings
- Specify Member Sampling Settings
- Specify Block Size
- Specify Property Restrictions
- Specify Unassigned Member Settings
- Disable the Checking of Aggregation Operators
- Report Against Time-Dependent Hierarchies
- Enable Support for Increased Number of Instances in a Request
- Build SAP VARIABLES Clauses Using Literal Strings

The following topics describe advanced set commands that allow you to customize your Adapter for SAP BW.

### Syntax: **How to Specify Empty Report Cell Settings**

ENGINE BWBAPI SET EMPTY {ON | OFF}

where:

**ON**

Indicates that empty cells are included in a report and all data is shown whether it is associated with a dimension member or not.

**OFF**

Indicates that empty cells are excluded from a report (if measures are referenced) and dimension data is not shown if no fact data is associated with the dimension member (if measures are not referenced). OFF is the default value.

**Tip:** You can change this setting from the Web Console by clicking *Data Adapters* in the navigation pane, clicking the name of a configured adapter, and choosing *Change Settings* from the menu.
Syntax: **How to Specify Member Sampling Settings**

During the synonym creation, member sampling is used to create Master File fields for dimension levels that precisely fit dimension member captions.

```
ENGINE BWBAPI SET MEMBER_SAMPLING {ON|OFF}
```

where:

**ON**

Indicates that the adapter will select all members of a hierarchy level to determine the optimum length for the field, and also the cardinality. The default value is ON.

**Note:** Depending on the data volume, this may take a long time. If synonym creation takes too long, you may wish to turn the MEMBER_SAMPLING OFF.

**OFF**

Indicates that all field lengths for the hierarchy levels are set to alphanumeric 60 and the cardinality information will be missing.

**Tip:** You can change this setting from the Web Console by clicking Data Adapters in the navigation pane, clicking the name of a configured adapter, and choosing Change Settings from the menu.

Syntax: **How to Specify Block Size**

SAP recommends fetching large row and cell sets by portions in order to avoid crashes in the SAP server. The BLOCK_SIZE setting sets the size of a portion.

```
ENGINE BWBAPI SET BLOCK_SIZE n
```

where:

**n**

Sets the size of a portion. 0 is the default value, which means all members of the result set are returned in one portion.

The value of this setting should not be changed unless there is a timeout. Contact Information Builders high-level tech support for further information on how to use this option.

**Tip:** You can change this setting from the Web Console by clicking Adapters, right-clicking the configured adapter, and choosing Change Settings. The Change Settings pane opens.

Syntax: **How to Specify Property Restrictions**

The ability to query on attribute values in the MEMBERS row set was made available with SAP BW 3.0B. (For details, see the SAP OSS Note 609314.)

```
ENGINE BWBAPI SET PROPERTY_RESTRICTIONS {ON|OFF}
```
where:

**ON**

Indicates that any tests on a dimension attribute will be sent to SAP.

It is recommended that you set PROPERTY_RESTRICTIONS to ON if your SAP BW release and patch level support the specifying restrictions on user-defined properties as selection tables. (Contact SAP support for exact list of releases and patch levels.)

**OFF**

Indicates that the filtering will be done on the WebFOCUS server. OFF is the default value.

**Tip:** You can change this setting from the Web Console by clicking *Adapters*, right-clicking the configured adapter, and choosing *Change Settings*. The Change Settings pane opens.

**Syntax:**

**How to Specify Unassigned Member Settings**

Sometimes dimension members are not explicitly arranged in a hierarchy. In SAP BW, assigned members are considered to be descendants of a root node named *All*, and unassigned members are considered to be children of a second root node named *All Not Assigned*. By default, Not Assigned members are not included in a report. You can include them using the INCLUDE_UNASSIGNED setting.

**ENGINE BWBAPI SET INCLUDE_UNASSIGNED {OFF|ACTIVE|ALL}**

where:

**OFF**

Does not include Not Assigned members belonging to an active hierarchy in a target report. OFF is the default value.

**ALL**

Includes all Not Assigned members belonging to an active hierarchy in a target report.

**ACTIVE**

Includes Not Assigned members belonging to an active hierarchy in which the lowest level is referenced. Individual unassigned members are listed at the lowest level of the hierarchy. This value is supported for level hierarchies only.

If the query does not include the lowest level, the summary for the Not Assigned nodes will not be shown unless there is a specific WHERE/IF statement at the lowest level.

**Tip:** You can change this setting from the Web Console by clicking *Adapters*, right-clicking the configured adapter, and choosing *Change Settings*. The Change Settings pane opens.
### Syntax: How to Disable the Checking of Aggregation Operators

If you specify prefix operators in the request, the adapter, by default, checks that they are compatible with the measure aggregators in the BW data. If any are not, a message is returned and the request is not processed. You can prevent the adapter from checking whether your operation matches the measure aggregator by issuing the CHECKAGGR OFF command.

```sql
ENGINE BWBAPI SET CHECKAGGR {ON|OFF}
```

- **ON**: Validates each prefix operator against the corresponding measure aggregator in BW. If a prefix operator does not match the corresponding measure aggregator, a message displays and the request is not processed. ON is the default value.
- **OFF**: Does not validate prefix operators against measure aggregators.

**Tip**: You can change this setting from the Web Console by clicking *Adapters*, right-clicking the configured adapter, and choosing *Change Settings*. The Change Settings pane opens.

### Syntax: How to Report Against Time-Dependent Hierarchies

When you report against a synonym with a time-dependent hierarchy, you use the `ENGINE BWBAPI SET KEY_DATE` command to set a key date for subsequent TABLE requests.

```sql
ENGINE BWBAPI SET KEY_DATE yyyymmdd
```

- **yyyymmdd**: Is the key date for the TABLE requests that follow. If you do not specify the key date, the current date is used as the key date. If you do not specify a correct key date (the one within the time period associated with the specified concurrent version of the hierarchy), your report will fail with an error message indicating absence of the specified hierarchy.

### Syntax: How to Enable Support for Increased Number of Instances in a Request

SAP has introduced a new set of OLAP BAPIs that support requests with more than one million instances per axis. The `SET USE_RSR_MDX` command enables the Adapter for SAP BW to take advantage of these new BAPIs.

```sql
ENGINE BWBAPI SET USE_RSR_MDX {OFF|ON}
```
where:

**OFF**

> Does not support requests with more than one million instances per axis. OFF is the default value.

**ON**

> Supports requests with more than one million instances per axis.

**Syntax:**

**How to Build SAP VARIABLES Clauses Using Literal Strings**

There are two different ways the adapter generates a SAP VARIABLES clause:

- Using literal strings.
- Using member unique names.

Using literal strings is perceived as more efficient because in this case the Adapter does not have to interact with the BW server in order to read the members of the hierarchy to obtain their unique names. However, generation of literal strings may or may not be possible depending on the types of tests against the variable fields and/or the type of the associated hierarchy and the variable selection type. Also, the success of an MDX request with literals depends on BW internal aspects which are not clearly documented by SAP.

The following setting controls whether the adapter will attempt to build a SAP VARIABLES clause using literals before resorting to the technique with member unique names:

**ENGINE BWBAPI SET USE_SAP_VARIABLE_LITERALS {ON|OFF}**

where:

**ON**

> Instructs the adapter to attempt to build a SAP VARIABLES clause using literals.

**OFF**

> Instructs the adapter to build a SAP VARIABLES clause using member unique names. OFF is the default value.
Support for BEx Structures

Example: Representing Structures as Dimensions or as a Cartesian Product

Structures consist of a group of characteristics and/or key figures. They can be saved and reused in other queries. For example, if plan/actual comparisons are being used extensively, it is possible to save a key figure group that consists of 10 key figures arranged for plan/actual comparison. To be able to use the same set of key figures in a different query, instead of selecting 10 key figures individually, adding the structure to the BEx query automatically brings those key figures into the query.

Note that SAP supports a maximum of two structures in a BEx query and only one of the structures can be of type Key Figure.

You can create a synonym with structured dimensions by checking the Structured Dimensions check box when creating the synonym.

Example: Representing Structures as Dimensions or as a Cartesian Product

You can represent structures as dimensions or create a cartesian product of the fields in the structures. Consider a BEx query that uses 2 structures:

- One structure is called *Curr. Year vs. Prev. year Cumulated* and it includes two time dimensions: Current Year and Prev.Year.

- The second structure is called *Orders-Sales-Returns* and it includes four key figures: Incoming Orders, Open Orders, Sales Volume, and Returns.

Without structured dimensions, the created Master File includes eight fields representing the cartesian product of the two structures. All of these fields are placed under the MEASURES section of the Master File and treated as separate key figures. The Master File looks something like this:

```
FILENAME=BW31C/Z2STRUCTURES_1KF_ROW_1COL, SUFFIX=BWBAPI , $
SEGMENT=Z2STRUCT, SEGTYPE=S0, $
$  -MEASURES-
  FIELDNAME=CURRENT_YEAR_CUMULATED_INCOMING_ORDERS,
  ALIAS=3466HXATG6RG1BG9GSTCN65IR3RV6E, USAGE=D18.2,
  ACTUAL=D8, MISSING=ON,
  TITLE='Current year cumulated Incoming Orders', $

  FIELDNAME=CURRENT_YEAR_CUMULATED_OPEN_ORDERS,
  ALIAS=3466HXATG6RG1BG9GSTCN65IR3RV6E, USAGE=D18.2,
  ACTUAL=D8, MISSING=ON,
  TITLE='Current year cumulated Open orders', $
```
FIELDNAME=CURRENT_YEAR_CUMULATED_SALES_VOLUME,
   ALIAS=3466HXATG6RG1BG9GSTCN65IR3RV6E, USAGE=D18.2,
   ACTUAL=D8, MISSING=ON,
   TITLE='Current year cumulated Sales Volume', $
FIELDNAME=CURRENT_YEAR_CUMULATED_RETURNS,
   ALIAS=3466HXATG6RG1BG9GSTCN65IR3RV6E,
   USAGE=D18.2, ACTUAL=D8, MISSING=ON,
   TITLE='Current year cumulated Returns', $
FIELDNAME=PREV__YEAR_CUMULATED_INCOMING_ORDERS,
   ALIAS=36AWN99ETKI46HMTOGIVHHS0J3RV6E,
   USAGE=D18.2, ACTUAL=D8, MISSING=ON,
   TITLE='Prev. year cumulated Incoming Orders', $
FIELDNAME=PREV__YEAR_CUMULATED_OPEN_ORDERS,
   ALIAS=36AWN99ETKI46HMTOGIVHHS0J3RV6E,
   USAGE=D18.2, ACTUAL=D8, MISSING=ON,
   TITLE='Prev. year cumulated Open orders', $
FIELDNAME=PREV__YEAR_CUMULATED_SALES_VOLUME,
   ALIAS=36AWN99ETKI46HMTOGIVHHS0J3RV6E,
   USAGE=D18.2, ACTUAL=D8, MISSING=ON,
   TITLE='Prev. year cumulated Sales Volume', $
FIELDNAME=PREV__YEAR_CUMULATED_RETURNS,
   ALIAS=36AWN99ETKI46HMTOGIVHHS0J3RV6E,
   USAGE=D18.2, ACTUAL=D8, MISSING=ON,
   TITLE='Prev. year cumulated Returns', $
$ DIMENSION 0DISTR_CHAN (Distribution Channel):
$ HIERARCHY (Distribution Channel):
... 
... 
The following is a sample WebFOCUS request against this Master File:

TABLE FILE Z2STRUCTURES_1KF_ROW_1COL
SUM CURRENT_YEAR_CUMULATED_INCOMING_ORDERS
   CURRENT_YEAR_CUMULATED_OPEN_ORDERS
   CURRENT_YEAR_CUMULATED_SALES_VOLUME
   CURRENT_YEAR_CUMULATED_RETURNS
   PREV__YEAR_CUMULATED_INCOMING_ORDERS
   PREV__YEAR_CUMULATED_OPEN_ORDERS
   PREV__YEAR_CUMULATED_SALES_VOLUME
   PREV__YEAR_CUMULATED_RETURNS
BY 0DISTR_CHAN_KEY
END
With structured dimensions, the created Master File includes four key figures placed under the MEASURES section of the Master File and the *Curr. Year vs. prev. year Cumulated* structure are treated as a dimension. The Master File looks something like this:

FILENAME= BW31C/Z2STRUCTURES_1KF_ROW_1COL_STON, SUFFIX= BWBAPI , $  
SEGMENT= Z2STRUCT, SECTYPE = S0, $  
$  -MEASURES-  
  FIELDNAME= INCOMING_ORDERS, ALIAS=[3RV6ENA572BRXFVFCKO2M2ZUWS],  
    USAGE= D18.2, ACTUAL= D8, MISSING= ON, TITLE='Incoming Orders', $  
  FIELDNAME= OPEN_ORDERS, ALIAS=[3RV6ENHTQ0XHG23VII4YD1TMK],  
    USAGE= D18.2, ACTUAL= D8, MISSING= ON, TITLE='Open orders', $  
  FIELDNAME= SALES_VOLUME, ALIAS=[3RV6ENPI8Z6YONBOC7AN3SCC],  
    USAGE= D18.2, ACTUAL= D8, MISSING= ON, TITLE='Sales Volume', $  
  FIELDNAME= RETURNS, ALIAS=[3RV6ENX6RY4WHB6RU69MX5R24], USAGE= D18.2,  
    ACTUAL= D8, MISSING= ON, TITLE='Returns', $  
$  DIMENSION 0DISTR_CHAN (Distribution Channel):  
$  HIERARCHY (Distribution Channel):  
...  
...  
$  DIMENSION EAZ5PAJIWG37DI674JZI2C3UB (Curr. year vs. prev. year  
    (cumulated to last period)):  
$  HIERARCHY (Curr. year vs. prev. year (cumulated to last period)):  
    FIELDNAME= CURR__YEAR_VS__PREV__YEAR__CUMULATED_TO_LAST_PERIOD_,  
      USAGE= A22, ACTUAL= A22, MISSING= ON,  
      TITLE='Curr. year vs. prev. year (cumulated to last period)',  
      WITHIN= '*[EAZ5PAJIG37DI674JZI2C3UB]', $  
$  Cardinality: 2  
$  DIMENSION EAZ5PAJIWG37DI674JZI2C3UB, PROPERTIES:  
    FIELDNAME= EAZ5PAJIWG37DI674JZI2C3UB_KEY, ALIAS= MEMBER_NAME,  
      USAGE= A64, ACTUAL= A64, MISSING= ON,  
      TITLE='Curr. year vs. prev. year (cumulated to last period) Key', $  

The following is sample WebFOCUS request against this Master File:

TABLE FILE Z2STRUCTURES_1KF_ROW_1COL_STON  
PRINT INCOMING_ORDERS  
  OPEN_ORDERS  
  SALES_VOLUME  
  RETURNS  
  BY CURR__YEAR_VS__PREV__YEAR__CUMULATED_TO_LAST_PERIOD_  
END
**Important:** If the BEx query includes only two structures and no dimensions as free characteristics or no dimensions in rows and columns, you should use structured dimensions. Without structured dimensions, the created synonym will have only measures and no dimensions. Any WebFOCUS requests created against such a synonym would produce the following messages:

(FOC11205) ERROR IN MASTER FILE DESCRIPTION:

(FOC11229) MDX SEGMENT DESCRIPTION CONTAINS NO HIERARCHIES

**Producing SAP BW Requests Using SQL**

**Example:**

- Retrieving Values From SAP BW
- Selecting Items From a Hierarchy
- Selecting a Complete Hierarchy Path

The following requests and output are examples of the capabilities of the Adapter for SAP BW using standard ANSI SQL code.

These examples require that you have created a synonym on the relevant tables from the Web Console. You can use the Web Console to navigate the SAP application hierarchy by searching the relevant tables or by doing a simple search by name.

**Note:** SQL does not support hierarchical reporting (BY HIERARCHY).

**Example: Retrieving Values From SAP BW**

The following syntax retrieves values from an SAP BW database:

```sql
SELECT SUM(DISBURSEMENT), ADDRESS1_LEVEL_01 FROM ZPAY4
GROUP BY ADDRESS1_LEVEL_01
ORDER BY ADDRESS1_LEVEL_01;
```

The output is:

<table>
<thead>
<tr>
<th>address1 Level 01</th>
<th>disbursement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1106 BROADWAY</td>
<td>132,242.33</td>
</tr>
<tr>
<td>11607 PACIFIC BLVD</td>
<td>9,174.96</td>
</tr>
<tr>
<td>11607 TREMONT AVENUE</td>
<td>14,849.56</td>
</tr>
</tbody>
</table>
### Example: Selecting Items From a Hierarchy

The following syntax selects items from a hierarchy in MARA:

```sql
SELECT SUM(SALES_VOLUME), SUM(INCOMING_ORDERS),
       PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_01,
       PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_02 FROM ZBIGQ
GROUP BY PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_01,
       PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_02
ORDER BY PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_01,
       PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_02
```

The output is:

<table>
<thead>
<tr>
<th>Product Hierarchy for material MARA Level 01</th>
<th>Product Hierarchy for material MARA Level 02</th>
<th>Sales Volume</th>
<th>Incoming Orders</th>
</tr>
</thead>
<tbody>
<tr>
<td>Foods</td>
<td>Bakery product; configured to order</td>
<td>.00</td>
<td>400.00</td>
</tr>
<tr>
<td>Hardware</td>
<td>PCs</td>
<td>85,159,860.98</td>
<td>86,754,997.71</td>
</tr>
<tr>
<td></td>
<td>Printer</td>
<td>.00</td>
<td>60,011.10</td>
</tr>
<tr>
<td>Lighting</td>
<td>Bulbs</td>
<td>62,235,898.00</td>
<td>62,674,320.00</td>
</tr>
<tr>
<td>Machines</td>
<td>Pumps</td>
<td>44,328,485.55</td>
<td>46,231,307.55</td>
</tr>
<tr>
<td>Paints</td>
<td>Gloss paints</td>
<td>.00</td>
<td>125.03</td>
</tr>
</tbody>
</table>
### Example: Selecting a Complete Hierarchy Path

The following syntax retrieves a complete hierarchy path from MARA:

```sql
SELECT SUM(SALES_VOLUME), SUM(INCOMING_ORDERS),
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_01,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_02,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_03,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_04
FROM ZBIGQ
GROUP BY
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_01,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_02,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_03,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_04
ORDER BY
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_01,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_02,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_03,
PRODUCT_HIERARCHY_FOR_MATERIAL_MARA_LEVEL_04;
```

The output is:

<table>
<thead>
<tr>
<th>Product Hierarchy for material MARA Level 01</th>
<th>Product Hierarchy for material MARA Level 02</th>
<th>Sales Volume</th>
<th>Incoming Orders</th>
</tr>
</thead>
<tbody>
<tr>
<td>Services</td>
<td>Maintenance</td>
<td>291,562.54</td>
<td>485,315.83</td>
</tr>
<tr>
<td>Vehicles</td>
<td>Cars</td>
<td>155,640.00</td>
<td>155,640.00</td>
</tr>
<tr>
<td></td>
<td>Motorcycles</td>
<td>41,761,619.76</td>
<td>42,494,811.00</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Product Hierarchy for material MARA Level 01</th>
<th>Product Hierarchy for material MARA Level 02</th>
<th>Sales Volume</th>
<th>Incoming Orders</th>
</tr>
</thead>
<tbody>
<tr>
<td>Foods</td>
<td>Bakery product; configured to order</td>
<td>.00</td>
<td>400.00</td>
</tr>
<tr>
<td>Product Hierarchy for material MARA Level 01</td>
<td>Product Hierarchy for material MARA Level 02</td>
<td>Product Hierarchy for material MARA Level 03</td>
<td>Product Hierarchy for material MARA Level 04</td>
</tr>
<tr>

Using the Adapter for SAP

The Adapter for SAP allows DataMigrator, WebFOCUS for SAP, and other applications to access SAP data sources. The adapter converts data or application requests into native SAP statements and returns optimized answers sets to the requesting program. For sample requests and output, see Producing SAP Requests on page 2244.

**Note:** The name SAP R/3 was used by SAP through Release 4.6. Other name variations in use by SAP are My SAP and SAP ECC. The WebFOCUS adapter services all of these variations.

**Topics:**

- Preparing the SAP Environment
- Accessing Multiple SAP Systems
- Configuring the Adapter for SAP
- Post-Configuration Tasks in an SAP Environment
- Managing SAP Metadata
- SAP Table Class Support for an Individual Table
- SAP Support for a Function Module
- SAP Data Type Support
- SAP Open/SQL Support
- Advanced SAP Features
- Setting Up the Report Processing Mode
- Supporting Mixed Code Page Environments
- Producing SAP Requests
Preparing the SAP Environment

In this section:
Preparing the SAP Environment for Adapter Components

Reference:
List of Authorization Objects, Fields, and Required Values for USER
List of Authorization Objects for Background Processing

The Server requires the SAP RFC SDK to communicate with the SAP Application Server. The location of the RFC SDK depends on the platform specific search path.

- **Platform dependent search path for shared libraries (RFC SDK):**

- **Windows:**
  - Directory where the executable is located.
  - Current directory.
  - Windows system directory and Windows directory.
  - Environment variable PATH.

- **AIX:**
  - Environment variable LIBPATH.

- **z/OS:**
  - Environment variable LIBPATH.

- **All other UNIX platforms:**
  - Environment variable LD_LIBRARY_PATH.

  If the server does not start, and indicates that some NLS libraries cannot be found, try:

  ```
  EXPORT NLSUI_7BIT_FALLBACK=YES
  ```

- **SAP/R3 support for IDOCs.** The Create Synonym function for IDOCs has been removed from the Web Console.
You can create synonyms for IDOCs using the method described below. However, while the adapter can read an external file that represents an IDOC, users are responsible for generating the external file and providing the DCB attributes associated with that external file. For information on specifying DCB attributes for a flat file representation of an IDOC, see the FILEDEF Command Under UNIX, Windows, IBM i, z/OS, and OpenVMS topic in the Stored Procedures Reference manual.

To create a synonym for SAP/R3 IDOC, a stored procedure (FOCEXEC) is supported, as shown in the following example:

```
CREATE SYNONYM i47_idocs/MATMAS03_edioff FOR MATMAS03 IDOC EDIOFF
   DBMS SQLSAP
   AT I47
   DROP
   END
```

You will use SAP GUI to logon to SAP and prepare the environment.

A Developer Key is required for the SAP user ID of the administrator. (The system prompts for the Developer Key if it has not been entered previously.)

USER IDs are required for authorization, with variations in privilege assignments based on the nature of the users responsibilities. Basic privileges are assigned to users who only need to execute procedures (focexecs). Administrative privileges are assigned to users who need to perform a variety of administrative functions for the Adapter for SAP. For example, the Adapter for SAP generates ABAP/4 programs dynamically at run time. This is done using adapter components uploaded into the SAP system during the configuration of the adapter, a task that requires administrative privileges.

For related information, refer to the following lists of processing objects: List of Authorization Objects, Fields, and Required Values for USER on page 2185 and List of Authorization Objects for Background Processing on page 2188.

**Reference:** List of Authorization Objects, Fields, and Required Values for USER

The following charts reflect any differences that apply for basic users and adapter administrators.

**S_RFC: Authorization check for RFC access**

</table>
Preparing the SAP Environment for Adapter Components

**How to:**

1. Log on to SAP.
2. Create a Development Class or Package.
3. Create a Function Group.
4. Deactivate the Unicode checks.
5. Activate a Function Group.

**Reference:**

- Customizing the Transport/Promotion of the ZXXX* Temporary Objects
- Transport Control

The Adapter for SAP generates ABAP/4 programs dynamically at run time. This is done using adapter components uploaded into the SAP system during the configuration of the adapter. Prior to uploading the components, the SAP system has to be prepared.

To prepare the SAP environment for the adapter components, perform the following steps:

1. Log on to SAP.
2. Create the Development Class or Package.
3. Create the Function Group.
4. Deactivate the Unicode checks.
5. Activate the Function Group.

---

### List of Authorization Objects for Background Processing

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>S_BTCH_ADM</td>
<td>N (unless you want the user to have administrative rights for Background jobs)</td>
</tr>
<tr>
<td>S_BTCH_JOB</td>
<td>RELE</td>
</tr>
</tbody>
</table>
Procedure: How to Log on to SAP

1. Launch SAP logon. In a standard SAP GUI installation, the executable file resides in \Program Files\SAP\FrontEnd\SAPgui\saplogon.exe. The SAP Logon dialog box opens.

If the list is empty, create a new entry.
Preparing the SAP Environment

a. Click New. The New Entry dialog box opens.

![New Entry dialog box]

b. Type the Description and Application Server, and select the System Number. In most cases, the SAP Router String is not needed, but check with your assigned SAP technical contact.

In the Application Server field, type either the SAP application server network name or IP address.

Click OK to create a new entry on the Logon list.

2. Select the entry on the list and click Logon.

A logon page prompting for a user ID and password appears. Logon to the system. Note that if the user ID is being used for the first time, the system will ask for the password to be changed.

Procedure: How to Create a Development Class or Package

Note: If you are using Release 4.7, create a Package instead of a Development Class.

1. Execute transaction SE80 to start the Object Navigator.

2. Type the Development Class or Package name for the installation of the Adapter for SAP (for example, ZIBI).

   Note: The Development Class or Package name can be a maximum of 14 characters and must follow SAP naming conventions for customer objects.
3. Click **Display**

   The system responds: Development Class or Package ZIBI does not exist.

4. Click **Yes** to create the object.

5. Type a short description for the Development Class or Package, for example, *IBI-Created*.

6. Accept all displayed defaults and click **Create**.

   The system generates a unique Change and Transport System (CTS) request #.

7. Save this CTS request # for deployment of the adapter to other SAP systems.

8. Click **Continue**.

### Procedure: How to Create a Function Group

1. Execute transaction SE80 to start the Object Navigator.

2. From the pull-down menu, select **Function Group**.

3. Type the same Development Class or Package name for the installation of the Adapter for SAP that you specified in *How to Create a Development Class or Package* on page 2190 (for example, ZIBI).

4. Click **Display**.

   The system responds: Function Group ZIBI does not exist.

5. Click **Yes** to create the object.

6. Enter a description for the Function Group.

7. Accept all displayed defaults and click **Save** (unless otherwise directed by an SAP Basis Administrator).

8. Under **Create Object Directory Entry**, type the same characters assigned to the Development Class and click **Save**.

9. Under **Prompt for transportable change request**, type the CTS request # assigned during the creation of the Development Class or Package.

10. Click **Continue**.

### Procedure: How to Deactivate the Unicode Checks

This procedure applies only to SAP Release 4.7.

1. Execute transaction SE80 to start the Object Navigator.

2. From the pull-down menu, select **Function Group**.
3. For Function Group value, type the name of the Function Group that you created (for example, ZIBI).

4. Click Display.

   The object window shows an open folder with the name of the function group and a closed folder named Includes.

5. Right-click the function group name (for example, ZIBI) and select Change from the pop-up menu.

   ![Change Function Group Window]

   6. Deselect the Unicode checks active check box and click Save.

   **Procedure:** How to Activate a Function Group

   1. Execute transaction SE80 to start the Object Navigator.
   2. From the pull-down menu, select Function Group.
   3. For Function Group value, type the name of the function group you created (for example, ZIBI).
   4. Click Display.

      The object window shows an open folder with the name of the function group and a closed folder named Includes.

   5. Right-click the function group name (in this example, ZIBI) and select Activate from the pop-up menu.

      A new window lists all inactive objects. Note that the object name now begins with SAPL.
Make sure the object for the function group ZIBI is selected.

6. Click Continue.

**Procedure: How to Verify a Function Group**

1. Execute transaction SE80 to start the Object Navigator.
2. From the pull-down menu, select Function Group.
3. For Function Group value, type the name of the function group created (for example, ZIBI).
4. Click Display.
5. Right-click the ZIBI folder and select Check - Extended Check.
6. Select Perform Check.

You should get a report with 0 errors, 0 warnings, and 0 messages.

**Note:** If you encounter errors or warnings during this step, resolve them at the SAP layer before continuing with the installation of the Adapter for SAP.

7. Double-click the error line for detailed information about the error.

The SAP environment is now prepared for the next step of function module upload from the Web Console.
**Reference: Customizing the Transport/Promotion of the ZXXX* Temporary Objects**

During the installation of the SAP adapter, a set of function modules, including some temporary objects like ZXXXBTCH and ZXXXREPTS, are uploaded and registered in the SAP repository. In preparation for the transport from the QA to DEV to PROD application servers, the ZXXXBTCH object must be assigned to the ZXXX development class. Otherwise, ZXXXBTCH will be assigned to the development class $TMP or remain unassigned, either of which can cause the transport to fail.

**Reference: Transport Control**

SAP provides a transport control program (tp) to handle release upgrades and transports among SAP systems. The transport control program:

- Keeps track of transports.
- Exports and imports objects in the correct order.
- Ensures that imports into a target system are performed in the same order as the exports from the source system(s). (Processing of imports out of order can result in severe inconsistencies in the target system, which are difficult to diagnose.)
- Enables you to perform exports and imports separately.

During an export, the objects to be transported are extracted from the database of the source system and stored in files of the operating system.

During the import, the objects are added to the database of the target system (according to the transport function recorded in the task).

**Note:** For detailed technical background, refer to [http://help.sap.com](http://help.sap.com).

**Accessing Multiple SAP Systems**

The adapter can operate across multiple SAP systems. In SAP, data from multiple companies can share the same metadata, and is identified by a client value. Normally, a given system has multiple clients, and you may access one or more of them depending on your authorization. For each system, the adapter requires one SAP logon consisting of a client, a user, and a password. This logon must be:

- RFC-enabled.
- Authorized for all clients that you may access.

You may need additional authorizations depending on the SAP data you wish to access. Consult your SAP administrator for details.
Configuring the Adapter for SAP

In this section:
Declaring Connection Attributes
Controlling Connection Scope
Controlling the Transmission of COMMIT Requests to SAP ECC
Installing and Verifying SAP Components

Configuring the Adapter for SAP consists of specifying connection and authentication information for each of the connections you want to establish.

In addition, you must install SAP components and, for SAP running on z/OS, you must install the SAP Code Page on the SAP server.

**Custom adapter configuration for accessing SAP BW Master Data tables.** Many organizations require analysis of Master Data in conjunction with Transactional Data in SAP BW.

- Transactional Data changes frequently (for example, account data, sales and purchase orders, and inventory). This data is stored in InfoCubes and is directly accessible through the Adapter for SAP BW, where it is available for up-to-the minute analysis.

- Master Data remains unchanged over a long period of time and is always needed in the same way (for example, access authorizations, standard printer information, and organization structures). However, this data is stored in BW Master Data Tables that may not initially be accessible in the cube-based SAP BW environment.

Since this complex analysis is predicated upon access to the Master Data, you must be able to make the Master Data tables accessible within the SAP BW environment. You can accomplish this by completing a simple configuration procedure using the table-based Adapter for SAP ECC. For details, see *How to Configure the Adapter for SAP ECC to Enable Access to SAP BW Master Data Tables* on page 2201.
## Declaring Connection Attributes

**How to:**
- Declare Connection Attributes
- Configure the Adapter on IBM Systems Using EBCDIC Character Sets
- Configure the Adapter for SAP ECC to Enable Access to SAP BW Master Data Tables

**Reference:**
- Connection Attributes for SAP

In order to connect to the SAP Application Server, the adapter requires connection and authentication information, which is supplied using the SET CONNECTION_ATTRIBUTES command.

You can enter connection and authentication information on the configuration pane of the Web or Data Management console. The command is added to the profile you select: the global server profile (edasprof.prf), a user profile (.user.prf), or a group profile (if supported on your platform). The global profile, edasprof.prf, is the default.

After configuring the adapter, you must install the static function modules in the SAP data dictionary to complete the configuration. For details, see *How to Install SAP Components* on page 2205.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*.
   
   or
   
   From the Data Management Console, expand the *Adapters* folder.
   
   The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.
   
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.
6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for SAP

The SAP adapter is under the ERP group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

User Authentication Parameters

The major work of the adapter is to translate user requests into code that can be understood by SAP. For this purpose, an SAP user ID, with a given set of privileges, is required. In the following list, this user ID is referred to as IBI_USER.

System

Name of the connection; maximum 12 characters.

Package Parameters

FPOOL

Function group where the Adapter for SAP static function modules can be cataloged. This is the function group created in Preparing the SAP Environment on page 2184.

RANGEBEG

Reserved for Information Builders use.

RANGEEND

Reserved for Information Builders use.

Connection Parameters

The Load Balancing check box determines which of the following options is exposed.

GROUP

Name of the application group. An application group defines a list of application servers, on which an RFC application can be running. SAP transaction SMLG can be used to view or modify application groups.

Note that the entries are case-sensitive and blank spaces are significant.

Appears only when Load Balancing is checked.

MSGHOST

Host name of the SAP system (message server).

Appears only when Load Balancing is checked.
**R3NAME**

System ID of the SAP system.
Appears only when Load Balancing is checked.

**HOST**

Host name of the SAP application server.

**GHOST**

Host name of the machine where the SAP gateway process is running. In the case where there is only one SAP application server, gwhost and host is the same.

**SYSNR**

SAP system number. This is a two-digit numeric value. Obtain this value from the SAP Administrator.

**CONNECTION LANGUAGE**

For SAP ECC Unicode configurations, you can select a language that is different from the language you use when logging on to the server (as determined by your NLS configuration).

From the CONNECTION LANGUAGE drop-down list on the Add SAP ECC non Unicode to Configuration pane, select the language you wish to use to connect to SAP ECC.

**Note:**

- When the CONNECTION LANGUAGE option is used to specify a language other than the one used for logging in to the server, the Create Synonym Multilanguage option is not available.

- For this option to work, the codepage of the iWay server must match the codepage of the SAP ECC server. For example, if the iWay server is configured FOR codepage 942 (SJIS), the SAP server must be configured for codepage 8000.

- There is no way to check if the requested connection language can be used by either the iWay server code page (either in terms of display or number of bytes) or the SAP ECC server.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).
Store the connection attributes in the server profile (edasprof).

**General User Login Parameters**

**Security**

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

**CLIENT**

SAP Client for the user logon, maximum 3 characters.

**USER**

SAP user ID for the user logon.

**PASSWORD**

SAP password for the user logon, maximum 8 characters.

Select the following check boxes, as required to:

- **Install Function Modules.** This option assumes that you have already completed the steps in *Preparing the SAP Environment* on page 2184, including creating a development class and Functions Group. To install the function modules for the adapter, select this check box. Ordinarily, function modules are installed only once. Reinstallation is required only if significant changes are made in the SAP system or if the Full-Function Server or the WebFOCUS Reporting Server is upgraded.

- **Overwrite Existing (with the same fully qualified name).** This option is displayed when you select Install Function Modules. Use it to ensure that newly installed function modules replace any older versions with the same name.

- **Initialize Metadata.** Before you create a SAP synonym, you must provide base metadata in the form of SAP synonym candidates. The Initialize Metadata option creates the base metadata for you. Ordinarily, you only need to initialize metadata once. The only reason to reinitialize metadata is if you reinstall the function modules.
**SNC Security Mode**

When SNC is checked, you must specify values for the following additional parameters:

**SNC_LIB**

SNC_LIB contains the path to the external security product library. The external security product’s library, external library, SNC_LIB, or gssapi library contains the functions provided by the external security product certified by SAP.

Set the environment variable SNC_LIB to contain the path to the security product library:

```
<drive>:\path\to\your\snclib.dll
```

**SNC_PARTNERNAME**

Is the external name of the SAP system. This is an extended version of the external name called the SNC name. You create the SNC name by providing a prefix with the external user name that designates the name type entered as follows:

```
<SNC-name_of_SAP_AppServer>
```

For example:

```
p/secude:CN=miller, OU=ADMIN, O=SAP, C=DE
p/krb5:miller@WDF.SAP-AG.DE
```

**Note about SNC with load-balancing.** Load-balancing or "group-logon" dynamically retrieves the target SNC-Name from the message server. When using SNC with load balancing, you must specify the following additional parameters:

```
SNC_PARTNERNAME=p:unused
SNC_LIB=<drive>:\path\to\your\snclib.dll
```

**Parameters for Mixed Character Code Sets**

The following section applies only when the server platform and the SAP instance platform do not use the same character code set (ASCII or EBCDIC).

**Procedure: How to Configure the Adapter on IBM Systems Using EBCIDC Character Sets**

To configure the adapter on IBM systems using the EBCIDC character set, the following code pages must be installed on the SAP server:

- In a z/OS environment, SAP code page 0126, or the correct code page for your language environment.

- For iSeries, SAP code page 0123, or the correct code page for your language environment.

1. Create two conversion tables as described in *Supporting Mixed Code Page Environments* on page 2238, and transfer the tables to the $EDACONF/etc directory.
For example, if the Server environment uses the code page 1100, then two conversion tables, 11000126.CDP and 01261100.CDP, should be created and transferred to the $EDACONF/etc directory.

2. The following environment variables are required at run time, assuming your code page is 0126:

   ```
   export SAP_CODEPAGE=0126
   export PATH_TO_CODEPAGE=$EDACONF/etc/
   ```

   **Note:** Make sure to include the trailing "/" for the value of the PATH_TO_CODEPAGE parameter and export the variables SAP_CODEPAGE and PATH_TO_CODEPAGE.

**Procedure:** How to Configure the Adapter for SAP ECC to Enable Access to SAP BW Master Data Tables

**Prerequisite:** The Adapters for SAP ECC and SAP BW must be installed. In addition, the Adapter for SAP BW must be properly configured and the Adapter for SAP ECC must be available for configuration as described below.

1. From the Web Console menu bar, select *Adapters*.

2. If the Adapter for SAP ECC has not yet been configured, click the *Adapters* folder in the navigation pane and choose *Add* from the menu. The Select Adapter to Add pane opens. Expand the *ERP* folder, expand the *SAP* folder, click a version of SAP, then click *Configure*. The Add SAP to Configuration pane opens.

   **Tip:** If the Adapter for SAP ECC has already been configured and appears in the list of Adapters in the navigation pane, and you can customize the configuration by clicking the current system connection and choosing *Properties*. The Change Connection Parameters pane opens, displaying the same parameters you would see on the Add to Configuration pane.

3. To establish the connection between the Adapter for SAP ECC and the SAP BW environment, enter values for the following configuration parameters, leaving the default values for the rest of the parameters on the configuration pane.

   **SYSTEM**

   Enter a descriptive name of up to 12 characters to specify the connection to the SAP BW system.

   **HOST**

   Enter the host name of the server on the SAP BW system.

   **Important:** This value, along with those for GWHOST and SYSNR, must match the corresponding values on the SAP GUI under System Entry Properties for SAP BW.
**GWHOST**

Enter the host name of the server where the SAP gateway process is running (in this case, the SAP BW system).

Generally, the entries for HOST and GWHOST are identical.

**SYSNR**

SAP system number. This is a two-digit numeric value.

4. Click *Configure*. You will see the message: *Connection successfully added to configuration*. The Adapter navigation pane displays the new SAP BW connection, illustrated as MU6_BW in the following example:

5. From the pop-up menu, you can now choose:

- **Test** to verify the connection. If the connection between the SAP ECC adapter and the SAP BW environment has been established, sample data will be returned in the right pane. A positive result also verifies that the SAP BW Master Data tables you need will be accessible in the SAP BW environment.
- **Create SAP Synonym** to create a synonym for an SAP BW Master Data Table. Continue to use the Adapter for SAP, following the standard procedure for creating a synonym against a TABLE object. (For details, see *Creation Parameters for Table Synonyms* on page 2212.)

In this case, the TABLE will be an SAP BW Master Data Table, made accessible and usable by your entries in step 3.

When prompted, enter the name of an SAP BW Master Data table, or select one from the list of tables, and click *Create Synonym*.

**Controlling Connection Scope**

**How to:**
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish. This setting enables you to control when the rfc api communications layer will be closed.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.
**Syntax:**

**How to Control the Connection Scope**

```sql
ENGINE SQLSAP SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

- **SQLSAP**
  Indicates the adapter. You can omit this value if you previously issued the `SET SQLENGINE` command.

- **FIN**
  Disconnects automatically only after the session has been terminated. FIN is the default value.

- **COMMAND**
  Disconnects automatically after each request. Depending on how often the event occurs, the `SET AUTODISCONNECT` command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

- **COMMIT**
  Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

**Controlling the Transmission of COMMIT Requests to SAP ECC**

**How to:**

Control the Transmission of COMMIT Requests to SAP ECC

The AUTOCOMMIT command controls when a COMMIT request is sent to SAP ECC.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax:**

**How to Control the Transmission of COMMIT Requests to SAP ECC**

```sql
ENGINE SQLSAP SET AUTOCOMMIT ON {FIN|COMMAND}
```

where:

- **SQLSAP**
  Indicates the adapter. You can omit this value if you previously issued the `SET SQLENGINE` command.
FIN
Sends the COMMIT request to SAP only after the session has been terminated.

COMMAND
Sends a COMMIT request to SAP each time the command is issued. COMMAND is the default value.

Installing and Verifying SAP Components

How to:
- Install SAP Components
- Verify Installation of SAP Components

After declaring connection attributes for SAP, to complete the configuration you must install and verify the SAP components.

Procedure: How to Install SAP Components

To install SAP components:

1. Launch the Web Console or the Data Management Console.
2. Access the list of configured adapters in the navigation pane.
3. Expand the SAP folder, then click the system you created when you set up user authentication parameters. For details, see Connection Attributes for SAP on page 2197.
4. Select Properties from the menu.
   The Change SAP System Connect Parameters pane opens. The Install SAP Components button is located at the bottom of the pane.
5. If you are re-installing due to an error in a previous installation, first select the Overwrite existing Function Group check box. A message warns that you are about to overwrite the function group, along with the associated function modules.
   If no error occurred, leave this box unchecked and proceed to step 6.
6. Click Install SAP Components. This process may take a few minutes. Do not close the browser window.
   A list of the function modules that have been installed is displayed.
7. To confirm the installation, see How to Verify a Function Group on page 2193.
**Procedure: How to Verify Installation of SAP Components**

To confirm that all necessary function modules have been successfully installed, as described in *How to Install SAP Components* on page 2205, complete the following steps:

1. From SAP run transaction SE80.
2. Select *Function Group* from the first drop-down list.
3. Type the name of the Function Group you created when you declared connection attributes. For details, see *Package Parameters* in *Connection Attributes for SAP* on page 2197.
4. Click *Display* next to the text box.
   
   Folders named Function Modules and Includes should be under the Function Group name.
5. Expand the Function Modules and Includes folders to verify that the following appears:

   - ZIBI_REP_CREATE
   - ZIBI_REP_GET_B_D
   - ZIBI_REP_ABORT_B
   - ZIBI_REP_DELETE
   - ZIBI_REP_RUN
   - ZIBI_TEST_REVERSE
   - ZIBI_DYNAMIC_RUN
   - ZIBI_GET_APPL_TREE
   - ZIBI_LDB_GET
   - ZIBI_SE80
   - ZIBI_REP_RUN_IN_B
   - ZIBI_REP_GET_B_S
   - ZIBI_DXOBJ_INFO
   - ZIBI_DD_FKEYS_GET

   **Note:** Z*** represents the name of the Function Group. If the Development Class and Function Group name is ZIBI, then the Function Module name begins with ZIBI.

---

**Post-Configuration Tasks in an SAP Environment**

*In this section:*

Customizing the Transport/Promotion of the ZXXXREPTS Temporary Object

During the installation of the Adapter for SAP, a set of function modules in the development class (ZXXX) is added to the SAP repository.

For details, see *Customizing the Transport/Promotion of the ZXXXREPTS Temporary Object* on page 2207.
Customizing the Transport/Promotion of the ZXXXREPTS Temporary Object

**Example:**
Transporting a Request

**Reference:**
Transport Data File Names
Change Request Information File
SAP Reserved Names

SAP provides a transport control program (tp) for controlling release upgrades and transports among SAP systems. The transport control program:

- Keeps track of transports.
- Exports and imports objects in the correct order.
- Ensures that imports into a target system are performed in the same order as the exports from the source system(s). (Processing of imports out of order can result in severe inconsistencies in the target system, which are difficult to diagnose.)
- Enables you to perform exports and imports separately.

During an export, the objects to be transported are extracted from the database of the source system and stored in files of the operating system.

During the import, the objects are added to the database of the target system (according to the transport function recorded in the task).

**Tip:** For detailed technical background, navigate to [http://help.sap.com](http://help.sap.com) (version 4.6C) and the menu path: SAP Library, Basis Components, Change and Transport System (BC-CTS), Transport Tools (BC-CTS-TLS), Transport Control Program tp. From here:

- Users should proceed to the section entitled *Preparing Operating System Users.*
- System administrators should proceed to the section entitled *Preparing the SAP System.*

**Reference:**  
**Transport Data File Names**

All data files are located in the transport directory data. The name of a data file consists of the name of the change request, and a code letter that distinguishes between data files generated by R3trans and those generated by application programs for application-specific development environment objects (ADOs):

- R <6 digits>.<source system> R3trans
D <6 digits>.<source system> application programs

Reference: Change Request Information File

The change request information file contains information about a change request, including the transport type and the class of the objects to be transported. It also contains information about the steps required for the change request, exit codes, and the time of execution.

This information file is located in the cofiles directory. The name is derived from the name of the change request:

K <6 digits>.<source system>

Reference: SAP Reserved Names

The Adapter for SAP is compatible with the SAP Basis 4.6C version, the lowest certified level for the adapter. It reserves the following names:

- Development class ZXXX
- Function Group ZXXX and function module names with ZXXX*

where:

xxx

Represents the 3 characters that are set by a certified SAP administrator to uniquely identify the client-independent table object and function modules. Note that a conflict with an existing unique name may cause the transport to fail.

Example: Transporting a Request

This illustration uses the sample request K900022 on P46. You may use it as a template for transporting a request.

Complete the following tasks in the order appropriate for each SAP system.

- Release the request from the sending system.
- Goto /usr/sap/transport/cofiles and copy K900022.P46 to the target system cofile directory.
- Goto /usr/sap/transport/data and copy R900022.P46 to the target system data directory.
- To check the transport system status of your SAP system, enter the command

```bash
tp checkimpdp <sapsid>
```
where:

\[ \text{sapsid} \]

Is the system ID. For example, P46, which is defined during the SAP system installation process.

- Check the status of the tp import buffer with the command:

  \[ \text{tp showbuffer } <\text{sapsid}> \]

**Tip:** Several tp commands are used in this procedure. For detailed information about tp procedures and commands, refer to the SAP tp documentation at http://help.sap.com.

- Clear the buffer using the command:

  \[ \text{tp cleanbuffer } <\text{sapsid}> \]

- Check the status to make sure all items have been cleared using the command:

  \[ \text{tp showbuffer } <\text{sapsid}> \]

- Add the transport using the command:

  \[ \text{tp add tobuffer P46K900022 } <\text{sapsid}> \]

- Check that the transport has been added to the buffer using the command:

  \[ \text{tp showbuffer } <\text{sapsid}> \]

- Import the transport using the command:

  \[ \text{tp import P46K900022 } <\text{sapsid}> \text{ ul} \]

  Note that you may need to add other options for override. For details, refer to the tp options documentation at http://help.sap.com.

- Verify that the ZXXX development class has been imported and activated, as indicated on your system screens.

### Managing SAP Metadata

**In this section:**

- Creating Synonyms
- Types of SAP Synonyms

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server accesses, you create a synonym that describes the structure of the data source and maps the server data types to the SAP data types.
Creating Synonyms

Synonyms define unique names (or aliases) for each SAP data object that is accessible from the server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File, which represent the server metadata.

Types of SAP Synonyms

How to:
Create a Synonym

Example:
Code Pages and Multilanguage Synonyms
SAP Query Synonym Variants
Creating a Synonym for an SAP Table

Reference:
Creation Parameters for Table Synonyms
Multilanguage Titles and Descriptions
Creation Parameters for LDB Synonyms
Limitations for Logical Databases
Creation Parameters for Function Module Synonyms
Creation Parameters for BAPI Synonyms
Limitations for Function Modules and BAPIs
Creation Parameters for Query Synonyms
Synonym Creation for IDOCs
Managing Synonyms

The Adapter for SAP enables you to create synonyms for:

- **Tables**
- **Logical Data Bases (LDBs) and Native LDBs**
For information that will help you determine when to use each type of LDB, see *Limitations for Logical Databases* on page 2218.

- **Business Application Programming Interfaces (BAPIs)**

  For information about requirements and limitations, see *Limitations for Function Modules and BAPIs* on page 2222.

- **Function Modules**

  For information about requirements and limitations, see *Limitations for Function Modules and BAPIs* on page 2222.

- **SAP Queries**

  An SAP query is a predefined report designed for users with little or no knowledge of the SAP programming language ABAP. From InfoSets (data sources), which are organized in user groups, an SAP query creates a list of information not already contained in the SAP system. This report may also include query variants within the global area. A variant is a saved set of selection criteria for a query or the report generated by the query. If you specify a variant when starting a query, the system uses the values in the variant for the query selection criteria.

  **Note:** IDOC synonyms are used for DataMigrator purposes and not for queries. Unlike other synonym types, you cannot create these synonyms from the Web Console. For more information, see *Synonym Creation for IDOCs* on page 2225. If an underlying IDOC changes, due to SAP requirements, regenerate your IDOC synonyms after assessing the impact on any active DataMigrator flows.

**Procedure:**  **How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**, then **New**, and then **Synonym**
   or

   From the Data Management Console, right-click an application directory, then select **New**, and then **Synonym**.

   The **Select adapter to configure** or **Select connection to create synonym** pane opens.

2. Click a connection for the configured adapter (or double-click in the Data Management Console).

   The first of a series of synonym creation panes opens.

3. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.
4. After entering the parameter values, click Create Synonym.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Reference:** *Creation Parameters for Table Synonyms*

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create the SAP synonym. These options appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

**Object Type**

Select TABLE from the drop-down list

**Multilanguage**

A synonym can be created using one or more languages. If you choose multiple languages, each selected language can have its own title and description attributes. For details on multilanguage titles and descriptions, see *Multilanguage Titles and Descriptions* on page 2215.

1. Click the Multilanguage check box to select languages in addition to the default logon language (the value of the SET LANGUAGE command at server startup). You get a list of available languages (the default language is not on the list).

2. Select one or more additional languages. For SAP, the WebFOCUS Reporting Server logon language is used to retrieve all languages.

**Note:** For the your language selections to be implemented, the selected languages must be installed. Also NLS must be enabled and consistent with your code page settings in the NLS Configuration Wizard. To access this wizard from the Web Console menu bar, select Workspace, Configuration. In the navigation pane, expand the General folder and click NLS. For related information, see *Code Pages and Multilanguage Synonyms* on page 2215.
Find by Tables or Views

On the next pane:

- Select a Find by option: Application Tree, Development Class, or Name. (These options mirror the way SAP organizes and filters its data.)

Subsequent selections vary depending on your Find method, as described below.

- Indicate whether to retrieve objects associated with Tables, Views, or both.

Application Tree. Choose this option, then click Next to retrieve a list of applications.

On the next pane, choose an application from the list, then click Next.

Development Class. Choose this option and type a Development Class name in the input box, or enter a string with wildcards, as needed. For example, enter: abc* (or abc%) to select development classes that begin with the letters abc; *abc (or %abc) to select those that end with the letters abc; *abc* (or %abc%) to select those that contain the letters abc at the beginning, middle, or end.

Click Next to display the Development Classe(s).

On the next pane, select a Development Class, then click Next.

Name. Choose this option and type the name of a Table in the input box, or enter a string with wildcards (* or %), as needed.

Enter a value in the Limit entry box. The default is 2000 tables. A message requesting a limit value is displayed when the list of available tables is too large to retrieve.

Click Next.

Choose the following options, as required:

Foreign keys

Click this check box if you wish to generate information about primary key and foreign key relationships in the Access File of the synonym.

An individual Master File is generated for each table. However, the relationships indicated in the Access File can be defined between any number of tables, and can reflect any number of levels of relationships among those tables.

Note: During synonym creation you may get one or more of the following messages:

(FOC44457) FOREIGN KEY FIELD **** CANNOT BE RESOLVED

(FOC44458) ONE OR MORE FIELDS OF THE FOREIGN KEY DO NOT EXIST

(FOC44459) MULTIPLE FOREIGN TABLES
where:

****

Is a table name.

These messages indicate that some of the foreign key relationships could not be resolved, and are, therefore, omitted during synonym creation. These messages are informational only: they should cause you no concern. In fact, the synonym is created and can be used in your requests without any problems.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**ODBC type fields**

Select this check box only if the synonym is to be used by an application that connects to the WebFOCUS reporting server via ODBC.

**Defines**

When this option is selected, unsupported formats trigger the creation of DEFINE (virtual) fields.

**From the list of tables at the bottom of the pane, choose those for which you wish to create synonyms:**

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.
Select objects for synonyms

Click the check box to the left of Default Synonym Name to generate synonyms for all listed tables, or check individual boxes in the same column to generate synonyms for the selected modules.

Reference:  Multilanguage Titles and Descriptions

When you create a Multilanguage synonym, title and/or description attributes for each selected language are added to the synonym. For example, if you choose French, the synonym will contain additional TITLE and DESC attributes of the following form:

```
TITLE_FR='french title'
DESC_FR='french description'
```

The default logon language generates titles and descriptions using the TITLE and DESCRIPTION attributes.

- If you set the LANGUAGE parameter to a language for which you generated additional title and description attributes, titles and descriptions are generated with the TITLE_In and DESC_In attributes (In being the two character ISO code; for example, EN, DE, JA).

- If you set the LANGUAGE parameter to a language for which you did not generate additional titles or descriptions, the TITLE and DESCRIPTION attributes are used to generate titles and descriptions.

In order to make field names in the synonym language independent, they are created based on the unique name of the field (these names are called technical names). In synonyms created using only the default language, field names are created based on the field caption.

Example:  Code Pages and Multilanguage Synonyms

The languages you wish to select for multilanguage synonyms determine which code page you should configure. For example, ISO 8859-1 can accommodate most Western European languages. Therefore, using this code page, you can request English, German, French, and Spanish.

The Unicode UTF-8 code page (65001) supports all languages and can therefore be used with any combination of languages. However, the UTF-8 character encoding scheme uses three bytes (in ASCII environments) or 4 bytes (in EDCDIC environments) to represent characters, increasing the storage needed for character data.
Reference: Creation Parameters for LDB Synonyms

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create the SAP synonym. These options appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

Object Type

Select LDB from the drop-down list.

Multilanguage

A synonym can be created using one or more languages. If you choose multiple languages, each selected language can have its own title and description attributes. For details on multilanguage titles and descriptions, see Multilanguage Titles and Descriptions on page 2215.

1. Click the Multilanguage check box to select languages in addition to the default logon language (the value of the SET LANGUAGE command at server startup). You get a list of available languages (the default language is not on the list).

2. You may select one or more additional languages. For SAP, the WebFOCUS Reporting Server logon language is used to retrieve all languages.

Note: For your language selections to be implemented, the selected languages must be installed. Also NLS must be enabled and your language selections must be consistent with your code page settings in the NLS Configuration Wizard. To access this wizard from the Web Console menu bar, select Workspace, Configuration. In the navigation pane, expand the General folder and click NLS. For related information, see Code Pages and Multilanguage Synonyms on page 2215.

Find by Native or Native Dynamic

On the next pane:

- Select a Find by option: Application Tree, Development Class, or Name. (These options mirror the way SAP organizes and filters its data.)

  Subsequent selections vary depending on your Find method, as described below.

- Indicate whether to retrieve objects associated with Native LDBs or Native Dynamic LDBs. For related information, see Limitations for Logical Databases on page 2218.

  In Native mode a static report is catalogued and executed.

  In Native Dynamic mode specific BAPIs are called to provide results on an LDB query.

Application Tree. Choose this option, then click Next.

On the next pane, choose an application from the list, then click Next.
Development Class. Choose this option and type a Development Class name in the input box, or enter a string with wildcards, as needed. For example, enter: abc* (or abc%) to select development classes that begin with the letters abc; *abc (or %abc) to select those that end with the letters abc; *abc* (or %abc%) to select those that contain the letters abc at the beginning, middle, or end.

Click Next to display the Development Classe(s).

On the next pane, select a Development Class, then click Next.

Name. Choose this option and type the name of a Table in the input box, or enter a string with wildcards (* or %), as needed.

Enter a value in the Limit entry box. The default is 2000 tables. A message requesting a limit value is displayed when the list of available tables is too large.

Choose the following options, as required:

Application
Select an application directory. The default value is baseapp.

Prefix/Suffix
If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms
To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

From the list of LDBs at the bottom of the pane, choose those for which you wish to create synonyms:

Default Synonym Name
This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select objects for synonyms
Select the objects for which you wish to create synonyms:

- For all objects, click the check box to the left of the Default Synonym Names column.
For specific objects, select the corresponding check boxes.

**Reference:** Limitations for Logical Databases

Synonym for SAP Logical Databases (LDB) can be generated in two different formats: SQL mode (set of joined SQL tables) or Native Mode (use of the underlying SAP Logical Database Program).

Note that in either mode, only the following LDBs are currently certified: VAV, SDF, KDF, CEK, CFK, CIK, CPK, CRK. Others need field certification.

- **SQL Mode.** Standard limitations concerning the number of Joins or number of fields in a synonym apply.

  From an end-user standpoint, SQL Mode usually runs faster, and is, therefore, the preferred method. Native Mode should be used only when there is a requirement to access so-called structures, for example, the segments SKC1A, SKC1C in SDF.

- **Native Mode.** Most LDBs in Native mode open a selection screen at run-time on which some of the parameters are required. Since the Adapter for SAP/R3-ECC works through RFC, it has no knowledge of this screen(s).

  This mode has two variations:

  - In Native mode, a static report is catalogued and executed.
  - In Native Dynamic mode, specific BAPIs are called to provide results on an LDB query.

**Reference:** Creation Parameters for Function Module Synonyms

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for a Function Module. You click the Create button to generate the synonym based on your entries.

Note that not all function modules are suitable for reporting.

**Object Type**

Select Function Module from the drop-down list.

**Multilanguage**

A synonym can be created using one or more languages. If you choose multiple languages, each selected language can have its own title and description attributes. For details on multilanguage titles and descriptions, see Multilanguage Titles and Descriptions on page 2215.

1. Click the Multilanguage check box to select languages in addition to the default logon language (the value of the SET LANGUAGE command at server startup). You get a list of available languages (the default language is not on the list).
2. You may select one or more additional languages. For SAP, the WebFOCUS Reporting Server logon language is used to retrieve all languages.

**Note:** For the your language selections to be implemented, the selected languages must be installed. Also NLS must be enabled and your language selections must be consistent with your code page settings in the NLS Configuration Wizard. To access this wizard from the Web Console menu bar, select *Workspace, Configuration*. In the navigation pane, expand the *General* folder and click *NLS*. For related information, see *Code Pages and Multilanguage Synonyms* on page 2215.

**Find by**

On the next pane, select a Find by option: *Application Tree, Development Class, or Name*. (These options mirror the way SAP organizes and filters its data.)

Subsequent selections vary depending on your *Find* method, as described below.

*Application Tree.* Choose this option, then click *Next*.

On the next pane, choose an application from the list, then click *Next*.

*Development Class.* Choose this option and type a Development Class name in the input box, or enter a string with wildcards, as needed. For example, enter: *abc* (or *abc*%) to select development classes that begin with the letters abc; *abc* (or %abc) to select those that end with the letters abc; *abc* (or %abc%) to select those that contain the letters abc at the beginning, middle, or end.

Click *Next* to display the Development Class(es).

On the next pane, select a Development Class, then click *Next*.

*Name.* Choose this option and type the name of a Table in the input box, or enter a string with wildcards (* or %), as needed.

Enter a value in the Limit entry box. The default is 2000 tables. A message requesting a limit value is displayed when the list of available tables is too large.

**Choose the following options, as required:**

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.
**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**From the list of tables (modules) at the bottom of the pane, choose those for which you wish to create synonyms:**

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Select objects for synonyms**

Click the check box to the left of *Default Synonym Name* to generate synonyms for all listed function modules, or check individual boxes in the same column to generate synonyms for the selected modules.

**Reference:** **Creation Parameters for BAPI Synonyms**

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create the SAP synonym. These options appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

**Object Type**

Select *BAPI* from the drop-down list.

**Multilanguage**

A synonym can be created using one or more languages. If you choose multiple languages, each selected language can have its own title and description attributes. For details on multilanguage titles and descriptions, see *Multilanguage Titles and Descriptions* on page 2215.

1. Click the *Multilanguage* check box to select languages in addition to the default logon language (the value of the SET LANGUAGE command at server startup). You get a list of available languages (the default language is not on the list).

2. You may select one or more additional languages. For SAP, the WebFOCUS Reporting Server logon language is used to retrieve all languages.
Note: For the your language selections to be implemented, the selected languages must be installed. Also NLS must be enabled and your language selections must be consistent with your code page settings in the NLS Configuration Wizard. To access this wizard from the Web Console menu bar, select Workspace, Configuration. In the navigation pane, expand the General folder and click NLS. For related information, see Code Pages and Multilanguage Synonyms on page 2215.

Find by

On the next pane, select a Find by option: Application Tree, Development Class, or Name. (These options mirror the way SAP organizes and filters its data.)

Subsequent selections vary depending on your Find method, as described below.

Application Tree. Choose this option, then click Next to retrieve a list of applications that contain BAPIs.

On the next pane, choose an application from the list, then click Next.

Development Class. Choose this option and type a Development Class name in the input box, or enter a string with wildcards, as needed. For example, enter: abc* (or abc%) to select development classes that begin with the letters abc; *abc (or %abc) to select those that end with the letters abc; *abc* (or %abc%) to select those that contain the letters abc at the beginning, middle, or end.

On the next pane, select a Development Class, then click Next.

On the next pane, choose an object type, then click Next.

Name. Choose this option and type the name of a BAPI in the input box, or enter a string with wildcards (* or %), as needed.

Enter a value in the Limit entry box. The default is 2000 tables. A message requesting a limit value is displayed when the list of available BAPIs is too large to retrieve.

On the next pane, select a BAPI, then click Next.

Choose the following options, as required:

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.
Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

From the list of BABIs at the bottom of the pane, choose those for which you wish to create synonyms:

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select objects for synonyms

Select the objects for which you wish to create synonyms:

- For all objects, click the check box to the left of the Default Synonym Names column.
- For specific objects, select the corresponding check boxes.

Reference: Limitations for Function Modules and BAPIs

- A function module must have at least one Import or Export parameter.
- When filtering with an internal table of type Select Option, any combination of conditions can be applied.
- Filtering with an internal table that is not of type Select Option is not supported.

Reference: Creation Parameters for Query Synonyms

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a QUERY synonym. These options appear on multiple panes. To advance from pane to pane click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

Object Type

Select QUERY from the drop-down list.

Cross Client Queries

SAP Queries can be created under two different query areas: Standard Area (client-specific) and Global Area (cross-client). By default, queries are created under the Standard Area so no action is required.

To create queries under the Global Area, select the Cross Client Queries check box.
**Important:** To be able to run WebFOCUS requests against queries that were originally created under the Global Area (cross-client), you must add the following selection criteria to the report request:

```
WHERE WORKSPACE EQ 'X';
```

**Filter by Group and Query**

To list queries for a specific Group, click the Filter checkbox and type a Group Name and/or a Query name in the input boxes provided, using the wildcard character (*) as needed.

**Select Candidates button**

Click to proceed to the next pane.

**Note:** If you receive the message No QUERYs Found, it is likely that the QUERY list was not generated.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**Select objects for synonyms**

Select the objects for which you wish to create synonyms:

- For all objects, click the check box to the left of the Default Table Names column.
- For specific objects, select the corresponding check boxes.

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.
Example: SAP Query Synonym Variants

When creating an SAP query synonym, all variants (if any) will be found at CREATE SYNONYM time. A two-segment Master File is created. The top segment holds the VARIANT field for all possible variants. The second segment is the actual report fields. A variant must be specified for running the report.

For example, with the following synonym:

```
$ $$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$ SNAPpack generated on Thu Feb 20 11:44:07 2003
$ SAP instance: I46  SAP Release: 46C
$ MFD generated for QUERY: BASEAPP/ALM01_02
$ $$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
FILE=BASEAPP/ALM01_02  ,SUFFIX=SQLSAP,
REMARKS='UG: 02 Query: ALM01',$
SEGNAME=VARIANT,SEGTYPE=S0,$
  FIELD=VARIANT, ALIAS=VARIANT,ACTUAL=A14,USAGE=A14,ACCEPT=
    'CAUS' OR
    'MY VARIANT' OR
    '
  ,$
SEGNAME=REPORT,PARENT=VARIANT,SEGTYPE=S0,$
  FIELD=SKA1_SAKNR, ALIAS=SKA1_SAKNR, USAGE=A010, ACTUAL=A010,
  TITLE='G/L acct', DESC='G/L account number',$
  FIELD=SKA1_GVTYP, ALIAS=SKA1_GVTYP, USAGE=A002, ACTUAL=A002,
  TITLE='AT', DESC='P&L statement account type',$
  FIELD=SKC1C_BUKRS, ALIAS=SKC1C_BUKRS, USAGE=A004, ACTUAL=A004,
  TITLE='CoCd', DESC='Company Code',$
  FIELD=SKC1C_GJAHR, ALIAS=SKC1C_GJAHR, USAGE=A004, ACTUAL=A004,
  TITLE='Year', DESC='Fiscal year',$
  FIELD=SKC1C_GSBER, ALIAS=SKC1C_GSBER, USAGE=A004, ACTUAL=A004,
  TITLE='BA', DESC='Business Area',$
  FIELD=SKC1C_HWAER, ALIAS=SKC1C_HWAER, USAGE=A005, ACTUAL=A005,
  TITLE='Crcy', DESC='Currency Key',$
  FIELD=SKC1C_UM01O, ALIAS=SKC1C_UM01O, USAGE=P16.2, ACTUAL=A16,
  TITLE='SKC1C-UM01', DESC='Monthly balance',$
  FIELD=SKC1C_HWAER1, ALIAS=SKC1C_HWAER1, USAGE=A005, ACTUAL=A005,
  TITLE='Crcy', DESC='Currency Key','$
```
A valid request using variant 'CAUS' is:

```
TABLE FILE ALM01_02
PRINT
  SKA1_SAKNR
  SKA1_GVTYP
  SKC1C_BUKRS
  SKC1C_GJAHR
  SKC1C_GSBER
  SKC1C_HWAER
  SKC1C_UM01O
  SKC1C_HWAER1
IF VARIANT EQ 'CAUS'
IF READLIMIT EQ 50
END
```

Note that the ACCEPT values list generated in the Master File for SAP Query Synonym Variants is optional. While a variant must be specified for running a report, you can choose to maintain your own variant list.

**Reference:** Synonym Creation for IDOCs

In previous releases of the server (5.3 through 7.1), support for IDOC synonyms was integrated into the Web Console. In Version 7 Release 6.x, IDOC synonym creation functions have been removed from the Web Console. This includes EDA (Electronic Data Interchange)/ALE (Application Link Enabling) options, which are no longer available on the Web Console.

Support for the creation of IDOC synonyms is now limited to read-only. You can create synonyms for IDOCs using the method described below. However, while the adapter can read an external file that represents an IDOC, users are responsible for generating the external file and providing the DBC attributes associated with that external file. (For related information that will be useful when specifying DCB attributes for a flat file representation of an IDOC, see the topic entitled *FILEDEF Command Under UNIX, Windows, IBM i, z/OS, and OpenVMS* in the *Stored Procedures Reference* manual.)

If you wish to generate an IDOC synonym, you can embed commands in a procedure (focexec), as shown in the following example:

```
CREATE SYNONYM i47_idocs/MATMAS03_edioff FOR MATMAS03 IDOC EDIOFF DBMS SQLSAP AT I47 DROP END
```
Example: Creating a Synonym for an SAP Table

The following synonym was generated from a TABLE source: DDO2T. The specified system name is 146. When the synonym is created, this value is reflected in the Access File.

Generated Master File DDO2T.mas

$$\text{SNAPpack generated on Tue Nov 26 17:42:06 2002}$

$$\text{SAP instance: I46 SAP Release: 46C}$

FILE=DD02T, SUFFIX=SQLSAP

REMARKS='R/3 DD: SAP table texts',$

SEGNAME=DD02T,SEGTYPE=S0,$

FIELD=DD02T_TABNAME, TABNAME, A30, A30, MISSING=OFF,

FIELD=DD02T_DDLANGUAGE, DDLANGUAGE, A1, A1, MISSING=OFF,

FIELD=DD02T_AS4LOCAL, AS4LOCAL, A1, A1, MISSING=OFF,

FIELD=DD02T_AS4VERS, AS4VERS, A4, A4, MISSING=OFF,

FIELD=DD02T_DDTEXT, DDTEXT, A60, A60, MISSING=OFF,

FILE=DD02T, SUFFIX=SQLSAP

REMARKS='R/3 DD: SAP table texts',$

**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. &lt;b&gt;Note:&lt;/b&gt; To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. &lt;b&gt;Note:&lt;/b&gt; This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numerc columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
**SAP Table Class Support for an Individual Table**

The ability of WebFOCUS to access a given table is based on its class. Class can be found in the TABCLASS field in DD02L for this particular table. The following table classes are supported.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data Management</strong></td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td><strong>Recreate DBMS Table.</strong></td>
<td>Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td><strong>Delete All Data.</strong></td>
<td>Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td><strong>Insert Sample Data.</strong></td>
<td>Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td><strong>Reorganize.</strong></td>
<td>Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This option is not available in the Web Console.</td>
</tr>
<tr>
<td><strong>Impact Analysis</strong></td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td><strong>Copy</strong></td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td><strong>Delete</strong></td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td><strong>Cut</strong></td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td><strong>Properties</strong></td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

---

**SAP Table Class Support for an Individual Table**

The ability of WebFOCUS to access a given table is based on its class. Class can be found in the TABCLASS field in DD02L for this particular table. The following table classes are supported.
<table>
<thead>
<tr>
<th>SAP Table Type</th>
<th>Server Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRANSP</td>
<td>Maps to an individual SQL table (called <em>transparent table</em> by SAP). It can usually be accessed and read by the interface (see exception 1).</td>
</tr>
<tr>
<td>INTTAB</td>
<td>Describes a structure (called <em>structure</em> by SAP) that can be used by function modules, logical databases, and so on. There is no underlying data, and it is not supported by the interface.</td>
</tr>
<tr>
<td>CLUSTER</td>
<td>These tables (called <em>cluster table</em> by SAP) are supported, as long as they satisfy exception 1.</td>
</tr>
<tr>
<td>POOL</td>
<td>These tables (called <em>pooled table</em>) are supported, as long as they satisfy exception 1.</td>
</tr>
<tr>
<td>VIEW</td>
<td>Those tables are supported, as long as they satisfy exception 1, and all joined tables carry a supported table class.</td>
</tr>
<tr>
<td>APPEND</td>
<td>These tables are not supported.</td>
</tr>
</tbody>
</table>

In addition, for all supported TABLE classes, they must be composed of a set of fields that have a supported data type. Unsupported data types are listed in exception 2.

**Exceptions:**

1. If a field in a table is of type RAW, with a significant length (for example, field CLUSTD in table INDX), this may indicate that the field may be used for import/export using a program. Since there is no information on the underlying structure, this field can only be printed as an alphanumeric string. Its corresponding contents may not be meaningful on display.

2. Unsupported data types: VARC, PREC, LCHR, LRAW, RAWSTRING.

**SAP Support for a Function Module**

There are two attributes (displayed in the *Attributes* tab of the function module) to consider before using a function module:

- If the function module is not released (displayed in *general data*), it is internal to SAP, and a user should use it with extreme caution. From release to release, this function module can be removed or its behavior changed without any SAP prior notice.
The attributes *normal function module* or *remote-enabled function module* described in the *Processing type* tab do not make a technical difference for the interface. However, if the function module is RFC-enabled, it may show that SAP has taken some steps to externalize this function module.

The interface is read-only. You should check that any function module called from the interface is read-only. There is no way for the server to check if a function module is read-only. This responsibility has to be deferred to the user.

Consideration should also be given to system security. If a function module is RFC-enabled, it does not mean it is bound to SAP security. From our own experience, only the subset of function modules with a name starting with *BAPI* may include SAP security.

### 1. Create Synonym Time

A function module may have a set of Import/Export/Changing/Tables parameters. It may also include a set of exceptions. (See current limitations below).

Every parameter must be prototyped to a data type that can be translated into a WebFOCUS server data type. If a parameter cannot be mapped, a warning is issued (FOC44492), and the parameter will be rejected. An example is the LOCAL_CAT import parameter in the READ_TEXT function module.

Parameters can be prototyped as LIKE or TYPE. In case of TYPE, this type must be externalized, that is, defined outside the scope of the function group where the function module is defined. An example where the TYPE cannot be found is in the SELKZ_KUPAV table parameter in the SD_PARTNER_SELECTION function module. This parameter is typed as LV09A_TY_PRTNR_ITAB, defined in the LV09A type group. In this case, an error message will be issued (FOC44488), and the parameter will be rejected.

The interface can handle either single fields or single-level structures, but it cannot handle compound structures, such as the IT_COMP_SIMUPARAM_RANGES import parameter in the ACEDS_ACCRUAL_FOR_ACRTYPE_CALC function module. In this case, an error message will be issued (FOC44491), and the parameter will be rejected.

When the structure of a table parameter contains only four contiguous fields named SIGN, OPTION, contains(LOW), and contains(HIGH), this particular table is viewed as a select option table, and will be declared as such in the Access File. This, outside of single-value import, is the most efficient way to pass a set of restrictions to a function module.

### 2. Limitations

- Currently the adapter does not support CHANGING parameters.
- Data type prototypes must be resolved to a real unique ABAP data type. As such, ANY, ANY TABLE, STANDARD TABLE, and TABLE are not supported as data type prototypes.
TYPE C defaults to A1.

TYPE STRING defaults to A80. For those two types (C and STRING), it will be up to the user, with the help of the Synonym Editor, to adjust the length of defined fields to individual needs.

Data type must be one that is supported. Unsupported data types are VARC, PREC, LCHR, LRAW, RAWSTRING.

IMPORT parameters can be mapped to one single field (using either LIKE or TYPE).

EXPORT parameters can be either single fields or a structure (using either LIKE or TYPE). When the EXPORT parameter is a structure defined using TYPE, there are two possibilities:

1. The parameter is referenced in the Data Dictionary as a structure (for example, BAPI RET2).
2. It is referenced as a Table type (for example, BAPI RET2_T).

Even though the synonym can be created in all cases, table type, as an export parameter is not supported.

3. Error/Warning Messages

- (E) (FOC44488) DATATYPE data_type NOT FOUND FOR PARAMETER parameter_name
- (E) (FOC44489) DDIF_FIELDINFO_GET INTERNAL ERROR FOR parameter_name
- (E) (FOC44490) DDIF_FIELDINFO_GET UNDOCUMENTED ERROR FOR parameter_name
- (E) (FOC44491) NESTED STRUCTURES NOT SUPPORTED. PARAMETER parameter_name
- (E) (FOC44492) PARAMETER parameter_name DOESN'T HAVE A DATA TYPE
- (W) (FOC44493) LIKELY SELECT OPTION TABLE table_name( parameter_name) WILL BE MAPPED TO AN INTERNAL TABLE

Upon error, if the parameter on which the error occurred is optional, the synonym will still be created without the corresponding parameter. If the parameter is required, the creation of the synonym will be aborted.

**Note:** Properties for a given parameter are found using the DDID_FIELDINFO_GET function module. If this function module cannot retrieve properties for the parameter, the parameter is flagged with (FOC44488).

ABAP exceptions generated by a SAP function module are now trapped at TABLE run time.
The resulting error will be:

(FOC1695) SAP/R3 REQUEST ERROR : 
[optional error message sent by the function module]

(FOC1736) SAP/R3 ERROR EXECUTING ABAP4 PROGRAM : function_module_name

**SAP Data Type Support**

The following table lists the SAP data types and notes how they are mapped to data types in the Master File.

<table>
<thead>
<tr>
<th>SAP Data Type</th>
<th>SAP Length</th>
<th>SAP Decimals</th>
<th>Usage</th>
<th>Actual</th>
</tr>
</thead>
<tbody>

<td>A2n</td>
<td>A2n</td>
</tr>
<tr>
<td>STRING</td>
<td>Maximum length 2GB</td>
<td>N/A</td>
<td>A80</td>
<td>A80</td>
</tr>
</tbody>
</table>

Note:

- * Date usage (DATS) * is dynamically determined based on the value of the country supplied in the general server configuration. Therefore, date presentations will vary by country.
- ** FLTP ** The value will be expressed as a floating point number with a mantissa and an exponent.

\[ D_{mm.ee}E \]

where:

- \( mm \) (mantissa)

  Is \( ee + 6 \). Adding 6 is the length in characters of \( \text{sign_of_mantissa} + \text{mantissa_digit} + \text{character 'D'} + \text{sign_of_exponent} + 2\)-digit exponent.
Is the number of SAP decimals -1 (SAP accounts for the decimal point in the count).

For example, the field UMREF in the table VBAP is a floating point number with 16 digits expressed as:

\[ ee = 16 \cdot 10^{-1} = 15 \text{. mm} = 15 + 6 = 21. \]

**FIELDNAME=VBAP UMREF, ALIAS=UMREF, USAGE=D21.15E, ACTUAL=D8**

*** STRING defines a variable character length sequence. If you need to adjust the length of the STRING, you can do so using the Web Console or Data Management Console Synonym Editor.

## SAP Open/SQL Support

The following table describes the conversion that takes place from the FOCUS statements to the SAP Open/SQL statements.

<table>
<thead>
<tr>
<th>FOCUS Command</th>
<th>Corresponding Open/SQL statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>READLIMIT</td>
<td>UP TO n ROWS</td>
</tr>
<tr>
<td></td>
<td>When a multiple SELECT statement is generated, READLIMIT is translated in UP TO n ROWS for each individual SELECT.</td>
</tr>
<tr>
<td>WHERE</td>
<td>Generally translated into a WHERE statement.</td>
</tr>
<tr>
<td>JOIN TO</td>
<td>For each table included in the JOIN command, embedded SELECT statements are created.</td>
</tr>
<tr>
<td>JOIN</td>
<td>Translated into SELECT ... SELECT SINGLE ...</td>
</tr>
<tr>
<td>NULL</td>
<td>The Adapter for SAP does not support the use of the reserved word 'NULL' as part of a WHERE clause. Including 'NULL' as part of a WHERE clause results in a syntax error.</td>
</tr>
<tr>
<td>SUM ... BY</td>
<td>By default, the aggregation feature is turned off. If the aggregation is turned off, individual rows are selected and aggregation and sorting is done by FOCUS. It can be turned on by issuing <strong>ENGINE SQLSAP SET OPTIMIZATION SQL</strong>.</td>
</tr>
<tr>
<td></td>
<td>Once the aggregation is turned on, the SUM is translated into SUM and the BY is translated into GROUP BY and ORDER BY.</td>
</tr>
<tr>
<td></td>
<td>The aggregation feature only applies to TRANSPARENT tables.</td>
</tr>
</tbody>
</table>
Advanced SAP Features

In this section:

- Support for User Security
- BAPI Support
- Join Support

This topic describes how to use security, BAPIs, joins, and tracing.

Support for User Security

The Native interface for SAP has been enhanced to handle the user ID and password in the following syntax:

```sql
ENGINE SQLSAP SET CONNECTION_ATTRIBUTES system/user,password:'client'
```

This feature allows you to run a secured request that involves the following:

- One or more BAPIs, as BAPIs are secured by SAP.
- SAP delivered logical databases, as the server code is secured by SAP.
- Function modules (either SAP or customer) that are fully prototyped, including the proper AUTHORITY-CHECK statements.
BAPI Support

This release supports most read-only BAPIs, including joins, as described in the following example:

```sql
CREATE SYNONYM baseapp/BUS0002_GETLIST
FOR BUS0002/GETLIST
BAPI DBMS SQLSAP AT I46
END
CREATE SYNONYM baseapp/BUS0002_GETDETAIL
FOR BUS0002/GETDETAIL BAPI
DBMS SQLSAP AT I46
END
JOIN BAPI0002_COMP_CODE IN COMPANYCODE_GETLIST TO
CCGD2_COMP_CODE IN COMPANYCODE_GETDETAIL
END
TABLE FILE COMPANYCODE_GETLIST
PRINT
CCGL0_TYPE NOPRINT
BAPI0002_COMP_CODE
BAPI0002_COMP_NAME
CCGD2_CURRENCY
CCGD2_LANGU
IF BAPI0002_COMP_CODE NE '2300' OR '6000'
END
```

Join Support

The Native Interface supports all joins from and to SAP. For performance reasons, we do not recommend joining to an SAP data source from a non-SAP data source. It is more efficient to hold the keys in a sequential file, and then use the following code:

```sql
TABLE FILE SAP PRINT FIELDS IF KEYS IS (HOLD) END
```

Setting Up the Report Processing Mode

**In this section:**

- Setting Dialog and Batch Execution Modes
- Setting Polling Intervals for Batch Execution

SAP supports many different types of processes (for example, batch, dialog (online), dynamic, print, and so on). Each WebFOCUS for SAP query creates a process within the SAP application server. This process can execute as either a dialog (online) or batch process.
These processing mode options allow you to adapt to the SAP application server configuration where there are a specific number of processes allocated for each process type per SAP application server.

You can change mode settings from the Web Console by clicking Data Adapters in the navigation pane, clicking the name of a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Setting Dialog and Batch Execution Modes**

You can set execution processing to dialog (also called online) mode or batch mode.

- **Dialog (or online) processing** is the default mode for the Adapter for SAP. An SAP dialog process is suitable for a task that needs to run immediately at a higher priority. An SAP dialog process is subject to an idle timeout limit where the default value is 15 minutes. Check with your SAP Basis consultant to see if this default value has changed. Dialog process mode should be set for reports that have processing times below the idle timeout limit. If the processing time of a report exceeds the dialog process idle timeout limit, the SAP application server terminates the process and the report fails to run.

In this mode, the report is executed online. The session is blocked until execution is completed. Execution time is bound to limits preset in the SAP system.

The following command sets your Adapter for SAP to dialog processing mode:

```
ENGINE SQLSAP SET EXECUTIONMODE ONLINE
```

You would use this command if you had explicitly set batch execution mode and wanted to switch back to dialog mode within a single session on the server.

If you have a WebFOCUS for SAP report that requires longer processing time, consider Batch processing.

- **Batch processing** is an alternative mode for the Adapter for SAP. An SAP batch process is suitable for a task that can afford to run in the background at a lower priority. This mode is for reports that require longer processing time (for example, reports that involve joining multiple tables or month end reports that need to process a lot of data). In this mode, the report will not time-out due to an execution time limit.

The following command will set your Adapter for SAP to batch processing mode:

```
ENGINE SQLSAP SET EXECUTIONMODE BATCH
```

To implement these settings from the Web Console, click Data Adapters in the navigation pane, click the name of a configured adapter, and choose Change Settings from the menu. The Change Settings pane opens. Choose Online or Batch from the Execution mode drop-down menu.

Note that you can also insert these commands directly into the server profile (for example, edasprof.prf) or included within the report procedure.
Setting Polling Intervals for Batch Execution

Before you issue any requests for batch execution, you can define how often the engine will check for the completion of these requests.

The syntax is

```
ENGINE SQLSAP SET NONBLOCK n
```

where:

- `n`

  Is the polling interval defined in number of seconds. The default is 30 seconds.

To implement this setting from the Web Console, click Data Adapters in the navigation pane, click the name of a configured adapter, and choose Change Settings from the menu. The Change Settings pane opens. Enter a value in the NONBLOCK field.

Note that you can also insert this command directly into the server profile (for example, edasprof.prf) or include it within the report procedure.

Supporting Mixed Code Page Environments

In this section:

Character Conversion Tables
Tracing Options

If you are using an SAP server that supports unicode, the adapter must also be configured for unicode. With this configuration, no character conversion tables are required.

If, however, you are using an older SAP server that does not support unicode the following information applies.

SAP, as well as adapters, can be installed on various platforms. If SAP is installed on a platform that uses a code page or character set different from the adapter platform, two character conversion tables must be generated to translate the different character sets, one for each direction of data flow.

For example, SAP is installed on an IBM i EBCDIC machine and the Adapter for SAP is installed on an Intel Windows ASCII machine. If a request is going from the server to SAP, an ASCII to EBCDIC translation is required. If SAP is sending data back to the Adapter for SAP, an EBCDIC to ASCII translation is required. This section describes how to create conversion tables and where they must reside.
Character Conversion Tables

**How to:**

Generate Conversion Tables
Download the Conversion Tables to the Server

SAP provides a transaction, SM59, to generate conversion tables for RFC-based applications such as the Adapter for SAP. Once these tables are created, they must be copied to the adapter.

**Procedure: How to Generate Conversion Tables**

1. Type transaction SM59 at the SAP GUI command line. The following window opens.
2. Select the Generate Conv. Tab option from the RFC pull-down menu. The following window opens.

![Conversion Table Generator](image)

3. Type a value for the Source code page, Target code page, and a valid path on the SAP application server where the conversion table file is created. Optionally, you can supply a valid path and a unique file name.

4. Click Execute.

   If you did not specify a unique file name, the default file name of the newly created conversion table will contain the source and target code page values. For example, if you specified a source code page of 0102 (IBM i for some CUAs) and a target code page of 1101 (7 bit USA ASCII pur), the default file name is 01021101.cdp. This is your IBM i (EBCDIC) to ASCII conversion table file.

   It is now necessary to create another conversion table file for translating code pages in the opposite direction.

5. Switch the source and target code pages and generate the conversion table.

   Continuing with previous example, you should have a source code page of 1101 and a target code page of 0102, resulting in a default file name of 11010102.cdp. This is your ASCII to IBM i (EBCDIC) conversion table file.
Note: If a unique file name was used for the first conversion table, be sure you specify a unique file name for the second conversion table.

**Procedure: How to Download the Conversion Tables to the Server**

Once these conversion table files are created, you can download them from the SAP application server directory to the server configuration ETC directory. Use SAP transaction AL11 to browse and download the two conversion table files to a local file on the desktop or Windows machine where the server is installed. Note that SAP GUI is required on the machine to which you are downloading the conversion table files. The following window represents transaction AL11.
1. Double-click the directory where the conversion table files were created. The following window opens.

2. Double-click the conversion table file to view its contents.
3. Select the List option from the System pull-down menu and select Save, then Local File as shown in the following image.

A dialog box displays prompting on a format for the transfer file.

4. Select unconverted format and click Continue.

5. Type a valid file name and click Transfer. This transfers the file to your local desktop.

6. Use any available editor on your desktop and remove the first three lines from the conversion table file. The following is an example of the text that should be removed:

```
Directory /tmp
Name: 01021102.CDP
```

After the edits have been made, configure the server with the Adapter for SAP. Once the adapter is configured, the conversion table files must be moved to the server EDAHOME ETC directory. Make sure both conversion table files are moved.
Tracing Options

Traces are enabled from the Web Console. Use the Custom option and select one of the following:

- SQLCALL
- SQLSAP/1
- SQLSAP/2
- SQLSAP/3

where:

- level

  Indicates the trace level. Currently supported trace levels are:

  - Generated ABAP/4 program.
  - Retrieved segments information.

You may also run a diagnostic trace from the SAP system by running transaction ST05 (Performance Trace). See your SAP system administrator for details.

Producing SAP Requests

Example:

- Retrieving All Records
- Retrieving Selected Fields
- Joining Two Tables

The following requests and output are examples of the capabilities of the Adapter for SAP using standard ANSI SQL code. These examples require that CREATE SYNONYM has been performed on the relevant tables from the Web Console. You can use the Web Console to navigate the SAP application hierarchy by searching the relevant tables or by doing a simple search by name.

Example: Retrieving All Records

The following syntax retrieves all records from T014:

```sql
SELECT * FROM T014;
```
WebFOCUS equivalent of this SQL statement is:

```
TABLE FILE T014
PRINT *
END
```

The output is:

```
All Codes Rep. Group Cred. Limit Risk Categ. FYI Variant Update Currency
.00000012EUR0001800
.00K4000012EUR1000800
.00K4000012USD3000800
.00K4000012JPY5000800
.00K4000012EURR100800
.00K4000012USDR300800
```

**Example: Retrieving Selected Fields**

The following syntax retrieves selected fields from MARA:

```
SELECT MARA_MATNR, MARA_MTART, MARA_MATKL, MARA_WRKST, MARA_BISMT FROM MARA WHERE MARA_MATKL='999';
```

The WebFOCUS equivalent of this SQL statement is:

```
TABLE FILE MARA
PRINT MARA_MATNR MARA_MTART MARA_MATKL MARA_WRKST MARA_BISMT
WHERE MARA_MATKL EQ '999';
END
```

The output is:

```
Matl_no Basic_matl Matl_group
999HALB 999
999KMATAM3-GT
```

---

Adapter Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS 2245
Example:  Joining Two Tables

The following syntax joins the MARA database with the MARC database:

```sql
SELECT MARA_MATNR, MARA_WRKST, MARC_WERKS FROM MARA, MARC WHERE MARA_MATNR = MARC_MATNR AND MARC_WERKS = '5100';
```

The WebFOCUS equivalent of this SQL statement is:

```webfocus
JOIN CLEAR *
JOIN MARA_MATNR IN MARA TO ALL MARC_MATNR IN MARC AS J0
TABLE FILE MARA
PRINT MARA_MATNR MARA_WRKST MARC_WERKS
WHERE MARC_WERKS EQ '5100';
END
```

The output is:

<table>
<thead>
<tr>
<th>Material</th>
<th>Basic_matl</th>
<th>Plant</th>
</tr>
</thead>
<tbody>
<tr>
<td>NC-100-212</td>
<td></td>
<td>5100</td>
</tr>
<tr>
<td>NC-100-213</td>
<td></td>
<td>5100</td>
</tr>
<tr>
<td>NC-100-311</td>
<td></td>
<td>5100</td>
</tr>
<tr>
<td>NC-100-312</td>
<td></td>
<td>5100</td>
</tr>
<tr>
<td>NC-103-101</td>
<td></td>
<td>5100</td>
</tr>
<tr>
<td>NC-103-211</td>
<td></td>
<td>5100</td>
</tr>
</tbody>
</table>
The Adapter for Siebel allows applications to access Siebel data sources. The adapter converts data or application requests into native Siebel statements and returns optimized answer sets to the requesting program.

Topics:
- Software Requirements for the Adapter for Siebel
- Preparing the Siebel Environment
- Preparing the Server Environment for Adapter Configuration
- Configuring the Adapter for Siebel
- Managing Siebel Metadata
- Optimization Settings
Software Requirements for the Adapter for Siebel

Verify that the level of Java 2 SDK required for your Siebel release is installed in your environment.

To do so, issue the following command from a command prompt:

```
Java -version
```

Then, check the version returned against your Siebel documentation. If a version is not returned, contact your system administrator.

Preparing the Siebel Environment

In this section:

- Setting Security
- Accessing a Server

To prepare the Siebel environment for adapter configuration, you must:

- [Setting Security](#) on page 2248
- [Accessing a Server](#) on page 2248

Setting Security

The Adapter for Siebel offers two methods of user authentication:

- **Explicit.** User IDs and passwords are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the Server’s global profile, edasprof.prf, for all users.

- **Password Passthru.** User ID and password received from the client application are passed to the Siebel Server for authentication. When a client connects to the server, the user ID and password are passed to Siebel for authentication and are not authenticated by the server.

Accessing a Server

Using the standard rules for deploying the Siebel Client, the server supports connections to:

- Local Siebel database servers.
- Remote Siebel database servers.
To connect to a Siebel database server, the server must be pointing to the correct Siebel Gateway Server, Siebel Enterprise Server, Siebel Object Manager, and Siebel Server on the target machine.

Once you are connected to a Siebel database server, that server may define Siebel DATABASE LINKs that can be used to access Siebel tables on other Siebel database servers.

Preparing the Server Environment for Adapter Configuration

In this section:
Defining Environment Variables

To prepare the server environment for adapter configuration, you must define environment variables.

In addition, if you are using Siebel 7.7 or higher and wish to take advantage of the Siebel native load balancing capability, you must add a property to the Siebel properties file and reference the associated directory in your CLASSPATH definition.

Defining Environment Variables

How to:
Define Configuration Environment Variables on Windows
Define Configuration Environment Variables on UNIX

Example:
Defining Configuration Environment Variables on Windows
Defining Configuration Environment Variables on UNIX

Reference:
Creating a Siebel Properties File for Load Balancing

The Adapter for Siebel requires two server environment variables.

Procedure: How to Define Configuration Environment Variables on Windows

1. Ensure that JAVA is in the application path. For example:

   PATH=c:\jdkVersion_number\bin

2. Point directly to the JVM.dll file in your path.
3. Add the Siebel jar files to the CLASSPATH, using the following syntax:

```
set CLASSPATH=jar1;jar2;[sieb_prop;%CLASSPATH%
```

where:

- **jdkVersion_number**
  Begins with jdk, followed by the Java 2 SDK version installed in your environment.

- **jar1**
  Is equal to the full path specification of the SiebelJI_Common Java Class file, SiebelJl_Common.jar or Siebel.jar (for version 7.7 and higher).

- **jar2**
  Is equal to the full path specification of the SiebelJI_enu Java Class file, SiebelJl_enu.jar.

- **sieb_prop**
  Is the directory in which the Siebel.properties file resides. This entry is required for load balancing with Siebel 7.7 or higher. For related information, see Creating a Siebel Properties File for Load Balancing on page 2251.

**Note:** Contact your Siebel Administrator for access to these Siebel Java Class files. These files must reside on the same machine as the Server. The files may be copied from a machine that has a Siebel installation.

**Example:**  
**Defining Configuration Environment Variables on Windows**

```
set CLASSPATH=D:\IBI\SiebelJl_enu.jar;D:\IBI\Siebel.jar
```

If you are using Siebel load balancing with Siebel 7.7 or higher, the following example would apply:

```
set CLASSPATH=D:\IBI\SiebelJl_enu.jar;D:\IBI\Siebel.jar;D:\IBI
```

**Procedure:**  
**How to Define Configuration Environment Variables on UNIX**

1. Export the JDK_HOME variable to point to the JAVA\bin directory. For example:

```
export JDK_HOME=/usr/javaVersion_number
```

2. Export the Shared Library variable to point to JAVA Home and the directory to LIBJVM shared library. For example:

```
export LD_LIBRARY_PATH=/usr/javaVersion_number/jre/bin/classic:/usr/javaVersion_number/jre/bin
```

3. Export the Siebel jar files to your CLASSPATH, using the following syntax:

```
export CLASSPATH=jar1;jar2;[sieb_prop;]$CLASSPATH
```
where:

javaVersion_number
  Begins with java, followed by the Java 2 SDK version installed in your environment.

jar1
  Is equal to the full path specification of the SiebelJl_Common Java Class file, SiebelJl_Common.jar or Siebel.jar (for version 7.7 and higher).

jar2
  Is equal to the full path specification of the SiebelJl_enu Java Class file, SiebelJl_enu.jar.

sieb_prop
  Is the directory in which the Siebel.properties file resides. This entry is required for load balancing with Siebel 7.7 or higher. For related information, see Creating a Siebel Properties File for Load Balancing on page 2251.

  Note: Contact your Siebel Administrator for access to these Siebel Java Class files. These files must reside on the same machine as the Server. The files may be copied from a machine that has a Siebel installation.

Example:  Defining Configuration Environment Variables on UNIX

```bash
export CLASSPATH=/u1/ibi/SiebelJl_enu.jar:/u1/ibi/Siebel.jar:$CLASSPATH
```

If you are using Siebel load balancing with Siebel 7.7 or higher, the following example would apply:

```bash
export CLASSPATH=/u1/ibi/SiebelJl_enu.jar:/u1/ibi/Siebel.jar:/u1/ibi:$CLASSPATH
```

Reference:  Creating a Siebel Properties File for Load Balancing

Beginning with Siebel 7.7, the Siebel Java Data Bean interface supports native round robin load balancing. To use this feature, you must add the following property to the siebel.properties file, assigning a list of Siebel servers with host names, port numbers, and server IDs to each virtual server. The syntax is

```bash
siebel.conmgr.virtualhosts=virtualserver1=sid1:host:port,sid2:host:port...;
[virtualserver2=..]
```

where:

virtualserver1
  Is the name you assign to the virtual server. You can define more than one virtual server with corresponding port, host, and sid#.
**port**

Is the default port number for the SCBroker (Siebel Connection Broker) component.

**host**

Is the machine name with Siebel Server installation.

**sid#**

Is the server ID.

See your Siebel documentation for additional information about Siebel load balancing.

---

## Configuring the Adapter for Siebel

### In this section:

Declaring Connection Attributes

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

## Declaring Connection Attributes

### How to:

Declare Connection Attributes

Declare Connection Attributes Manually

### Example:

Declaring Connection Attributes

### Reference:

Connection Attributes for Siebel

---

In order to connect to Siebel, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).
You can declare connections to more than one Siebel data source by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to Siebel takes place when the first query that references that connection is issued.

If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*.
   
or

   From the Data Management Console, expand the *Adapters* folder.
   
The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.
   
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

**Reference: Connection Attributes for Siebel**

The Siebel adapter is under the *ERP* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.
**Gateway server: gateway port #**

Siebel Gateway Server name.

For Siebel version 7.7 and higher, you must also supply the Gateway server port #.

**Enterprise server**

Siebel Enterprise Server name.

**Object Manager**

Siebel Object Manager name.

**Siebel server**

Siebel Server name. Siebel Server name.

*Note:* This parameter is not required for Siebel version 7.7 and higher.

**Siebel repository**

Name of the repository from which to read Siebel metadata.

**Security**

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

**User**

Username by which you are known to Siebel. This field only displays when the security mode of the server is non-trusted.

**Password**

Password associated with the user name. This field only displays when the security mode of the server is non-trusted.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).
Store the connection attributes in the server profile (edasprof).

**Syntax:** How to Declare Connection Attributes Manually

**Explicit.** The user ID and password are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the Server's global profile, edasprof.prf, for all users.

```sql
ENGINE SIBIN SET CONNECTION_ATTRIBUTES connection_name /userid,password;'Gateway/Enterprise/Obj Mngr/Siebel'
```

**Password Passthru.** The user ID and password received from the client application are passed to the Siebel Server for authentication. When a client connects to the server, the user ID and password are passed to Siebel for authentication and are not authenticated by the server.

```sql
ENGINE SIBIN SET CONNECTION_ATTRIBUTES connection_name :'Gateway[:gateway port_#]/Enterprise/Obj Mngr/Siebel'
```

where:

SIBIN
- Indicates the adapter.

connection_name
- Is a logical name used to identify this particular set of connection attributes. In the Access File, it becomes the CONNECTION= attribute.

userid
- Is the primary authorization ID by which you are known to Siebel.

password
- Is the password associated with the primary authorization ID.

'Gateway/Enterprise/Obj Mngr/Siebel'
- Is the Siebel connection string. This information must be supplied.

Gateway[:gateway port #]
- Is the Siebel Gateway Server name. For Siebel version 7.7 and higher, you must also supply the Gateway server port #.

Enterprise
- Is the Siebel Enterprise Server name.

Obj Mngr
- Is the Siebel Object Manager name.
Siebel

Is the Siebel Server name. This parameter is not required for Siebel version 7.7 and higher.

Example: Declaring Connection Attributes

Explicit authentication:

ENGINE SIBIN SET CONNECTION_ATTRIBUTES CON1
/USER_ID, PASSWORD;:'ARIBA01/ARIBA01/SCCObjMgr/SiebelSrv'

Password Passthru authentication:

ENGINE SIBIN SET CONNECTION_ATTRIBUTES CON2
:'devportal2/siebel/EAIObjMgr/devportal2'

Managing Siebel Metadata

In this section:

Creating Synonyms
Data Type Support

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Siebel data types.
Creating Synonyms

How to:
Create a Synonym
Set Visibility Mode

Example:
Creating a Synonym
Using Visibility Mode in a Report Request
Using Visibility Mode in a SQL Request

Reference:
Synonym Creation Parameters for Siebel
Managing Synonyms
Access File Attributes

Synonyms define unique names (or aliases) for each Business Component (BC) that is accessible from a server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.
4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

**Reference:** Synonym Creation Parameters for Siebel

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

**Filter by Business Objects**

Select this option to filter the Business Objects for which you wish to create synonyms.

When you filter by name, the Business Object Name input box is displayed. Enter a string for filtering the Business Objects, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter ABC% to select Business Objects which begin with the letters ABC; %ABC to select Business Objects which end with the letters ABC; %ABC% to select Business Objects which contain the letters ABC at the beginning, middle, or end.

**Select BOs button**

Click this button to display the Business Objects that meet the specified criteria.

**Filter Business Components**

Select this option to filter the Business Components for which you wish to create synonyms. When you choose to filter, the Business Component Name input box is displayed.
Enter a string for filtering the Business Component, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter ABC% to select Business Component which begin with the letters ABC; %ABC to select Business Component which end with the letters ABC; %ABC% to select Business Component which contain the letters ABC at the beginning, middle, or end.

**Select Company Object**

Select the business object for which you want to see business components.

**Select BCs button**

Click this button to display the Select Business Components. All Business Components that meet the specified criteria appear.

**Validate**

Select the **Validate** check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2821 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: ‘; ': ' \: '/'; ' ; ' $'. No checking is performed for names.

**Make unique**

Select the **Make unique** check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the **Overwrite existing synonyms** check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select Business Object and Component

☐ To select all Business Objects/Business Components in the list, select the check box to the left of the Default Synonym Name column heading.

☐ To select specific Business Objects/Business Components, select the corresponding check boxes.

Example: Creating a Synonym

To generate a synonym for the ACCOUNT Siebel Business Object and Siebel Business Component, enter the following information on the Create Synonym panes of the Web Console or the Data Management Console:

1. Click the Filter Business Objects check box, enter ACCOUNT in the Name field, and click the Select BOs button.

2. On the second Create Synonym pane, click the Filter Business Components check box, enter ACCOUNT, and click the Select BCs button.

3. Select Account in the Default Synonym name column.

4. Click Create Synonym. The synonym is created and added under the specified application directory (baseapp is the default).

   A status window displays the message: All Synonyms Created Successfully

5. From the message window, click Applications on the menu bar.

6. Open the baseapp application folder in the navigation pane and click the synonym account.

7. Choose Edit as Text from the menu to view the generated Master File, then choose Edit Access File as Text to view the corresponding Access File.

  .
  .
  .
The Master File root segment describes the Siebel Business Component. All scalar fields of the Business Component are described as fields in the root segment. All Multi Value fields (MVG) of the Business Component are described as descendant segments of the root. The name of the segment representing an MVG is derived from the Business Component Multi Value field name. All other Multi Value fields related to the same Multi Value Link are not shown in the Master File. The MVG segment contains references to the appropriate fields in the linked Business Component instead. All scalar fields of the MVG are described as fields in the MVG segment. All MVG fields of an MVG become descendant segments of the segment representing this parent MVG.

Master File field aliases represent real Siebel Business Component field names. Long names (between 67 and 75 characters) are stored in the Access File. Corresponding Master File fields must have no aliases. Similarly, long segment names are stored in the Access File as well.

A special virtual field VISIBILITY_MODE is added to the root segment to enable the client to set the visibility type for the Business Component. Available visibility modes are enumerated in the ACCEPT parameter for this field. Siebel Versions 6 and 7 support different sets of visibility modes, which is reflected in the ACCEPT list.

The visibility modes are:

Siebel v7: SalesRep, Manager, Personal, All, Organization, Contact, Group, Catalog, and SubOrganization.
Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
### Option

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Management Followed by these options, if applicable:</td>
</tr>
<tr>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Syntax:**

**How to Set Visibility Mode**

**IF VISIBILITY_MODE EQ 'All'**

This syntax tells Siebel to look at the user ID referenced in the .prf file and according to that user's ID authorization privileges, Siebel returns a view of ALL for the requested output.

If no visibility mode is set in the report, it defaults to the personal visibility mode.
**Example:** Using Visibility Mode in a Report Request

The following request prints the NAME field where the VISIBILITY MODE is set to All.

```plaintext
TABLE FILE ACCOUNT
  PRINT NAME VISIBILITY_MODE
  WHERE ( VISIBILITY_MODE EQ 'All' )
  AND ( NAME LIKE '%WLI%' )
END
```

The output is:

<table>
<thead>
<tr>
<th>NAME</th>
<th>VISIBILITY_MODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yelena WLI 81 0129 iway55</td>
<td>All</td>
</tr>
<tr>
<td>Yelena WLI 81 0129 iway55 JCA2</td>
<td>All</td>
</tr>
<tr>
<td>Yelena WLI 81 IDE</td>
<td>All</td>
</tr>
</tbody>
</table>

**Example:** Using Visibility Mode in a SQL Request

The follow selects NAME and VISIBILITY_MODE based on VISIBILITY MODE and wildcards in NAME.

```sql
SELECT NAME, VISIBILITY_MODE FROM ACCOUNT
WHERE VISIBILITY_MODE = 'All' AND NAME LIKE '%WLI%'
END
```

The output is:

<table>
<thead>
<tr>
<th>NAME</th>
<th>VISIBILITY_MODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yelena WLI 81 0129 iway55</td>
<td>All</td>
</tr>
<tr>
<td>Yelena WLI 81 0129 iway55 JCA2</td>
<td>All</td>
</tr>
<tr>
<td>Yelena WLI 81 IDE</td>
<td>All</td>
</tr>
</tbody>
</table>

**Reference:** Access File Attributes

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONNECTION=connection_name</td>
<td>Indicates access to specified Siebel Server. Defaulted to the default connection.</td>
</tr>
<tr>
<td>SEGNAME</td>
<td>Name of the corresponding segment in the Master File.</td>
</tr>
<tr>
<td>SEGNAME_LONG</td>
<td>Long (1 to 75 characters) Siebel segment name.</td>
</tr>
</tbody>
</table>

<tr>
<td>REPOSITORY</td>
<td>Siebel Repository.</td>
</tr>
</tbody>
</table>

Data Type Support

All Siebel scalar, alphanumeric, and currency fields are treated as alphanumeric fields. All Siebel date and integer fields are supported.

Optimization Settings

**How to:**
Specify Block Size for Array Retrieval

**Example:**
Testing Retrieval Performance

The Adapter for Siebel supports array retrieval from result sets produced by executing SELECT queries or stored procedures. This technique substantially reduces network traffic and CPU utilization.

The block size for a SELECT request applies to TABLE FILE requests, MATCH requests, and DIRECT SQL SELECT statements.

**Syntax:**

How to Specify Block Size for Array Retrieval

```plaintext
ENGINE SIBIN SET FETCHSIZE n
```

where:

**SIBIN**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**n**

Is the number of records to be passed from the physical layer of the adapter, written in Java, to the logical layer, implemented in C. Accepted values are 1 to 5000.

1 indicates non-blocked communication. 1 is the default value.
This value is associated with all data retrieval operations and applicable to all segments.

**Example: Testing Retrieval Performance**

The following procedure uses the FETCHSIZE command to test retrieval performance. It shows the difference in milliseconds based on the FETCHSIZE.

```
-DEFAULT &FS = 50
SET PANEL=999
ENGINE SIBIN SET FETCHSIZE 1
-RUN
-SET &&STARTCPU = &FOCCPU;
-RUN
TABLE FILE ACCOUNT
SUM NAME ACCOUNT_COMPETITORS
ON TABLE HOLD
END
-RUN
-SET &DIFFCPU = &FOCCPU - &&STARTCPU;
-TYPE1 CPU FetchSize= 1 : &DIFFCPU MS
-RUN
ENGINE SIBIN SET FETCHSIZE &FS
-RUN
-SET &&STARTCPU = &FOCCPU;
-RUN
TABLE FILE ACCOUNT
SUM NAME ACCOUNT_COMPETITORS
ON TABLE HOLD
END
-RUN
-SET &DIFFCPU = &FOCCPU - &&STARTCPU;
-TYPE1 CPU FetchSize= &FS : &DIFFCPU MS
```
The Adapter for SQLBase allows applications to access SQLBase data sources. The adapter converts application requests into SQLBase calls and returns optimized answer sets to the requesting application.

Topics:
- Preparing the SQLBase Environment
- Configuring the Adapter for SQLBase
- Managing SQLBase Metadata
- Customizing the SQLBase Environment
- Optimization Settings
Preparing the SQLBase Environment

How to: Set Up the Environment on Windows and UNIX

In order to use the Adapter for SQLBase, you must install the SQLBase driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running. The Adapter for SQLBase only supports access to U.S. databases.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the SQLBase Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX or IBM i location for some JDBC Driver files to /usr/driver_files/mydriver.jar, issue the commands:

   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH

   Similarly, on Windows, you would issue the command:

   set CLASSPATH=c:\usr\driver_files\mydriver.jar:%CLASSPATH%

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace

   edastart -show

   and check the special services section displays "JSCOM3 active".

   If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server’s EDAPRINT. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the Server Installation manual.
Configuring the Adapter for SQLBase

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

How to:
- Declare Connection Attributes
- Declare Connection Attributes Manually

Example:
- Declaring Connection Attributes

Reference:
- Connection Attributes for SQLBase

In order to connect to a SQLBase data source, the adapter requires connection and authentication information.

You supply this information using the \texttt{SET CONNECTION\_ATTRIBUTES} command. You can enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one SQLBase data source using the \texttt{SET CONNECTION\_ATTRIBUTES} commands. The actual connection takes place when the first query is issued. If you issue multiple \texttt{SET CONNECTION\_ATTRIBUTES} commands:

- The connection named in the first \texttt{SET CONNECTION\_ATTRIBUTES} command serves as the default connection.
- If more than one \texttt{SET CONNECTION\_ATTRIBUTES} command contains the same connection name, the adapter uses the attributes specified in the last \texttt{SET CONNECTION\_ATTRIBUTES} command.
Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   
or
   From the Data Management Console, expand the Adapters folder.
   
The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for SQLBase

The SQLBase adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**URL**

Location URL for the SQLBase data source.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**Driver name**

Name for the SQLBase JDBC driver.
See SQLBase documentation for the specific driver release you are using.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax: How to Declare Connection Attributes Manually**

```
ENGINE SQLBAS SET CONNECTION_ATTRIBUTES connection 'URL'/userid,password
```

where:

- **SQLBAS**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  
  Is the connection name.

- **URL**
  
  Is the URL to the location of the SQLBase data source.

- **userid**
  
  Is the primary authorization ID by which you are known to the target database.

- **password**
  
  Is the password associated with the primary authorization ID.

**Example: Declaring Connection Attributes**

The following SET CONNECTION_ATTRIBUTES command connects to a books database using the SQLBase Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

**Note:** Consult vendor documentation for the exact name, port, and path.

```
ENGINE SQLBAS SET CONNECTION_ATTRIBUTES CON1 'jdbc:sqlbase://edared30:2155/island'
```
Overriding the Default Connection

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

If multiple connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

**Syntax:**
**How to Change the Default Connection**

ENGINE SQLBAS SET DEFAULT_CONNECTION connection

where:

SQLBAS
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

FOC1671, Command out of sequence

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  FOC1671, Command out of sequence.

**Example:**
Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects CON1 as the default connection.

ENGINE SQLBAS SET DEFAULT_CONNECTION CON1
Controlling the Connection Scope

**How to:**

Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:**

How to Control the Connection Scope

```sql
ENGINE SQLBASE SET AUTODISCONNECT ON {FIN | COMMIT}
```

where:

- **SQLBASE**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **FIN**
  
  Disconnects automatically only after the session has been terminated. FIN is the default value.

- **COMMIT**
  
  Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing SQLBase Metadata

**In this section:**

- Identifying the Adapter
- Accessing Database Tables
- Creating Synonyms
- Data Type Support
- Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.
Identifying the Adapter

**How to:**

Identify the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLBAS to identify the Adapter for SQLBase.

**Syntax:**

How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLBAS [,,$]
```

where:

- **file**
  - Is the file name for the Master File. The file name without the .mas extension can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

- **SQLBAS**
  - Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using SQLBase, you must locally install the RDBMS SQLBase Driver.

The Server can access third-party database tables across the network SQLBase. You must specify a URL for the data source and, possibly, a user ID and/or password for the database you are accessing. You can define these parameters in either the server global profile or in a user profile.
Creating Synonyms

How to:
Create a Synonym

Example:
Sample Generated Synonym

Reference:
Synonym Creation Parameters for SQLBase
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Note: If you are creating a synonym for a SQLBase data source, you must first add the syntax SET SYNONYM=BASIC to the edasprof.prf file.

Procedure: **How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.
5. After entering the parameter values, click Create Synonym.

   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

**Reference: Synonym Creation Parameters for SQLBase**

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
Object name. Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the Base Location field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the Document Name field, enter the file name with or without wild card characters.
- In the Document Extension field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the Base Location field, enter:
  
  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

  The Document Extension is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

`DATASET=/ul/home2/apps/report3.sql`

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the Cardinality check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
**With foreign key**

Select the *With foreign key* check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Customize data type mappings**

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support* on page 2284.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Owner/Schema**

The user account that created the object or a collection of objects owned by a user.

**Type**

The object type (Table, View, and so on).

**Select tables**

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the **Select All** button.
- To select specific tables, select the corresponding check boxes.

**Example: Sample Generated Synonym**

An Adapter for SQLBase synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

**Master File nf29004.mas**

```plaintext
FILE=DIVISION, SUFFIX=SQLBASE,$
SEGNAME=SEG1_4, SEGTYPE=S0,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF,$
```

**Access File nf29004.acx**

```plaintext
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=CON1,KEYS=1,WRITE=YES,$
```

**Reference: Access File Keywords**

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td><strong>Keyword</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>TABLABNAME</td>
<td>Identifies the SQLBase table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLABNAME= [owner.]table</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is: CONNECTION = connection CONNECTION=' ' indicates access to the local data source. Absence of the CONNECTION attribute indicates access to the default database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first n fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>KEYFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td>IXFLD</td>
<td>KEYFLD is the FIELDNAME of the common column from the parent table.</td>
</tr>
<tr>
<td></td>
<td>IXFLD is the FIELDNAME of the common column from the related table.</td>
</tr>
<tr>
<td></td>
<td>KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. <strong>Note:</strong> An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.</td>
</tr>
</tbody>
</table>
**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td>Note:</td>
<td>To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td>Note:</td>
<td>This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
Option | Description
--- | ---
Data Management | Followed by these options, if applicable:

**Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)

**Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted.

**Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values.

**Reorganize.** Recreates the data source table preserving original data.

**Note:** This option is not available in the Web Console.

Impact Analysis | Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS* manual for details about Impact Analysis reports.

Copy | Copies the synonym to the clipboard.

Delete | Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.

Cut | Deletes the synonym and places it on the clipboard.

Properties | Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

**Data Type Support**

Data types are specific to the underlying data source.
### Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>How to Override the Default Precision and Scale</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENGINE SQLBAS SET CONVERSION RESET</td>
<td></td>
</tr>
<tr>
<td>ENGINE SQLBAS SET CONVERSION format RESET</td>
<td></td>
</tr>
<tr>
<td>ENGINE SQLBAS SET CONVERSION format [PRECISION precision [scale]]</td>
<td></td>
</tr>
<tr>
<td>ENGINE SQLBAS SET CONVERSION format [PRECISION MAX]</td>
<td></td>
</tr>
</tbody>
</table>

**where:**

- **SQLBAS**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **RESET**
  Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

- **format**
  Is any valid format supported by the data source. Possible values are:
  - **INTEGER** which indicates that the command applies only to INTEGER columns.
  - **DECIMAL** which indicates that the command applies only to DECIMAL columns.
  - **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
FLOAT which indicates that the command applies only to double-precision floating-point columns.

precision

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

scale

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

MAX

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
Setting the Precision and Scale Attributes

Example: Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```
ENGINE SQLBAS SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```
ENGINE SQLBAS SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```
ENGINE SQLBAS SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```
ENGINE SQLBAS SET CONVERSION RESET
```

Customizing the SQLBase Environment

In this section:

- Specifying a Timeout Limit
- Cancelling Long Requests
- Obtaining the Number of Rows Updated or Deleted

The Adapter for SQLBase provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

How to: Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to SQLBase.

Syntax: How to Issue the TIMEOUT Command

```
ENGINE SQLBAS SET TIMEOUT {nn|0}
```
where:

SQLBAS
   Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE
   command.

nn
   Is the number of seconds before a time-out occurs. 30 is the default value.

0
   Represents an infinite period to wait for a response.

Cancelling Long Requests

How to:
   Cancel Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities
of the native JDBC driver, this action will either cancel the request entirely or break out of
the fetch cycle.

Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose Workspace, Configuration/Monitor, Java Services,
   DEFAULT. Right-click on DEFAULT and select Agents.

2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill,
   right-click on it and select Stop.

Obtaining the Number of Rows Updated or Deleted

How to:
   Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru
INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters
on the menu bar, clicking a configured adapter, and choosing Change Settings from the
menu. The Change Settings pane opens.
Syntax:  How to Obtain the Number of Rows Updated or Deleted

ENGINE SQLBASE SET PASSRECS {ON|OFF}

where:

SQLBASE

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Optimization Settings

In this section:

Optimizing Requests
Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

**How to:**
Optimize Requests

**Example:**
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

**Reference:**
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

```sql
SQL SQLBAS SET {OPTIMIZATION|SQLJOIN} setting
```

where:

- **SQLBAS**
  
  Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

- **SQLJOIN**
  
  Is a synonym for OPTIMIZATION.

- **setting**
  
  Is the optimization setting. Valid values are as follows:

  - **ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

  - **OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:** SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLBAS SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
  FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
  FOR FETCH ONLY;
```

**Example:** SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLBAS SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

AGGREGATION DONE ... 
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT) 
FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2 
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS') 
GROUP BY T2.EID, T1.LN 
ORDER BY T2.EID, T1.LN;

**Reference:** SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:**
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.
**Syntax:**

How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLBAS SET OPTIFTHENELSE {ON | OFF}
```

where:

- **SQLBAS**
  - Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

- **ON**
  - Enables IF-THEN-ELSE optimization. This is the default.

- **OFF**
  - Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:**

Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
SQL SQLBAS SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = ' ') AND (T1.'FN' = ' '))
    AND (T1.'DPT' = 'MIS'));
```
Example: **Using IF-THEN_ELSE Optimization With Aggregation**

Consider the following request:

```sql
SQL SQLBAS SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = 'SMITH')));
```

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

Example: **Using IF-THEN_ELSE Optimization With a Condition That Is Always False**

```sql
SQL SQLBAS SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  \[ X = X + 1; \]
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

**Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Optimization Settings
The Adapter for SQL Server Analysis Services (SSAS) allows applications to access SQL Server Analysis Services data sources.

The adapter converts application requests into Multidimensional Expressions (MDX), which it submits to SQL Server Analysis Services and returns the resulting data to the WebFOCUS Reporting Server.

**Topics:**

- Preparing the SQL Server Analysis Services (SSAS) Environment
- Configuring the Adapter for SQL Server Analysis Services
- Managing SQL Server Analysis Services Metadata
- Customizing the SQL Server Analysis Services Environment
- SQL Server Analysis Services (SSAS) Reporting With WebFOCUS
Preparing the SQL Server Analysis Services (SSAS) Environment

In this section:
Setting SQL Server Analysis Services (SSAS) Security
Accessing SQL Server Analysis Services

How to:
Set Up the Environment

The Adapter for SQL Server Analysis Services minimally requires the installation of the Microsoft OLE DB Provider for Analysis Services 9.0, 10.0, or 11.0, which is part of the Microsoft Data Access Components (MDAC) installation.

Procedure: How to Set Up the Environment

Microsoft OLE DB Provider for Analysis Services 9.0, 10.0, or 11.0 must be installed in your system.

The Adapter for SQL Server Analysis Services provides read-only access to analytical data stored in cubes. The adapter is an OLE DB for OLAP consumer. It employs Multidimensional Expressions (MDX) language to access aggregated or rolled-up data used for decision-support processing.

You can use any server front-end technology with the WebFOCUS reporting engine to access the OLAP data retrieved by the server for Windows. This makes your OLAP data available to your entire enterprise. Additionally, data from SSAS cubes can be joined with data from any other supported data source, providing additional information to your analytical process.

Setting SQL Server Analysis Services (SSAS) Security

There are three methods by which you can be authenticated when connecting to SQL Server Analysis Services:

Operating System (Trusted) mode. The user ID and password used to log on to the operating system are automatically used to connect to the Analytical Engine. The server data access agent impersonates an operating system user according to the server deployment mode. The agent process establishes a connection to a SSAS based on the impersonated operating system user credentials.
SSAS recognizes the security restrictions that the OLAP Database Administrator specifies and applies them to catalogs and cubes. This includes the role of security on the database and the application level. Although the Server for Windows establishes the connection to SSAS, an impersonation of the client is used to maintain access privileges.

- **Security off.** If the Server is running with security off, the user ID and password of the interactive user (the person logged onto a Windows or Workstation) is passed to the Analytical Engine in order to establish a connection and access rights. This is the logon ID specified for the Windows or Windows Workstation after it is first started.

- **Security on.** If the Server is running with security on, the user ID and password of the client connecting to the server is passed to the Analytical Engine in order to establish a connection and access privileges. This process is called impersonation.

**Explicit mode.** The user ID and password are explicitly specified for each connection and passed to SQL Server Analysis Services, at connection time, for authentication.

**Password passthru mode.** The user ID and password are explicitly specified for each connection and passed to SQL Server Analysis Services, at connection time, for authentication.

### Accessing SQL Server Analysis Services

Using the standard rules for deploying OLE DB, the server supports connections to:

- Local SQL Server Analysis Services.

- Remote SQL Server Analysis Services. (To connect to a remote SSAS instance, you must have Microsoft OLE DB Provider for Analysis Services 9.0 installed in your system.)

### Configuring the Adapter for SQL Server Analysis Services

**In this section:**

Declaring Connection Attributes

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Reference:
Connection Attributes for SQL Server Analysis Services (SSAS)

The SET CONNECTION_ATTRIBUTES command allows you to declare a connection to one SQL Server Analysis Services.

You can declare connections to more than one Analytical Engine by issuing multiple SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query referencing that connection is issued. You can include those commands in an RPC or a server profile. The profile can be encrypted.

If you issue multiple SET CONNECTION_ATTRIBUTES commands, the first command sets the default SQL Server Analysis Services to be used.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   or

   From the Data Management Console, expand the Adapters folder.

   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.
Connection Attributes for SQL Server Analysis Services (SSAS)

The SQL Server Analysis Services adapter is under the OLAP group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**Server**

Name of the machine where SQL Server Analysis Services (SSAS) is running. If that machine has more than one instance of SQL Server Analysis Services (SSAS) installed, provide the server name and the instance name as follows: server\instance.

**Security**

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).
**Syntax:**

**How to Declare Connection Attributes Manually**

**Trusted authentication.** The adapter connects to SQL Server Analysis Services (SSAS) as an operating system login using the credentials of the operating system user impersonated by the server data access agent.

```
ENGINE SSAS SET CONNECTION_ATTRIBUTES [connection]server/
```

**Explicit authentication.** The user ID and password are explicitly specified for each connection and passed to SQL Server Analysis Services (SSAS), at connection time, for authentication as a standard login.

```
ENGINE SSAS SET CONNECTION_ATTRIBUTES [connection]server/user,pwd
```

**Password passthru authentication.** The user ID and password received from the client application are passed to SQL Server Analysis Services (SSAS), at connection time, for authentication as a standard login.

```
ENGINE SSAS SET CONNECTION_ATTRIBUTES [connection]server
```

where:

- **SSAS**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQL ENGINE command.

- **connection**
  - Is a logical name used to identify this particular set of attributes.
  - If you plan to have only one connection to SQL Server Analysis Services, Is the server name used as a connect descriptor to the SQL Server Analysis ServicesServer across the network..

- **server**
  - Is the machine where SQL Server Analysis Services is running.

- **user**
  - Is the primary authorization ID by which you are known to SQL Server Analysis Services.

- **pwd**
  - Is the password associated with the primary authorization ID.
Managing SQL Server Analysis Services Metadata

In this section:
- Creating Synonyms
- Converting Alphanumeric Dates to WebFOCUS Dates

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the SQL Server Analysis Services data types.

Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Creating a Synonym

**Reference:**
- Synonym Creation Parameters for SQL Server Analysis Services (SSAS)
- Selecting Valid Dimensions for a Measure
- Managing Synonyms
- Access File Keywords

Synonyms define unique names (or aliases) for each Analytical Engine cube that is accessible from a server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

For details on how to create a synonym through the Web Console, see the Server Configuration and Operation manual for your platform.
Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

Reference: Synonym Creation Parameters for SQL Server Analysis Services (SSAS)

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

Filter by Catalog and Cube Name

If you wish to filter your selections, click this check box and enter a catalog and/or cube name in the input boxes.
You can enter a full catalog or cube name or use a wildcard character (%) as needed, at the beginning and/or end of the string. For example, enter: ABC% to select catalogs or cubes that begin with the letters ABC; %ABC to select catalogs or cubes that end with the letters ABC; %ABC% to catalogs or cubes that contain the letters ABC at the beginning, middle, or end.

**Field Name Case**

Select whether you want mixed-case or uppercase field names. Mixed-case is the default value.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

*Note:* The connected user must have operating system write privileges in order to recreate a synonym.

**Include System-Enabled Hierarchies**

To include all hierarchies, not just user-defined hierarchies, in the synonym, select the Include System-Enabled Hierarchies check box.

**Present parent/child hierarchies as**

Select how you want parent/child hierarchies represented in the synonym:

- As parent/child hierarchies, the default. This option creates a set of fields for each parent/child hierarchy that describe a member’s position in the hierarchy. To report from a parent/child hierarchy use the BY HIERARCHY syntax to automatically retrieve, display, and format portions of the hierarchy with appropriate indentations to identify the hierarchical relationships between the members.

- As level hierarchies. This option creates separate fields for each hierarchy level. To report from this type of hierarchy, specify the field name for each level of the hierarchy you want to display as a BY field in the request.
**Select cubes**

Select the cubes for which you wish to create synonyms:

- To select all cubes in the list, select the check box to the left of the Default Synonym Name column heading.
- To select specific cubes, select the corresponding check boxes.

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Example: Creating a Synonym**

To generate a synonym for the Sales cube in the FoodMart 2000 Data Warehouse, enter the following information on the Create Synonym panes of the Web Console or the Data Management Console:

1. On the first Create Synonym pane, click the Filter by Catalog and Cube Name check box.
2. Enter Food% in the Catalog field and S% in the Cube Name field.
3. Click the Next button.
4. On the second Create Synonym pane, select Sales from the list of displayed cubes in the FoodMart 2000 catalog.
5. Click Create Synonym. The synonym is created and added under the specified application directory (The default is baseapp).

   A status window displays that the synonym was created successfully.

6. Open the baseapp application folder in the navigation pane and click the synonym Sales.
7. Choose Edit as Text from the menu to view the generated Master File, then choose Edit Access File as Text to view the corresponding Access File.

**Generated Master File**

**Note:** Master Files should not be altered. Manipulating the Master File causes incorrect query results.

The Measures dimension can contain calculated and non-calculated members. Calculated members in the Measures dimension will contain a Reference defining the calculated member and a Property. Some properties are mandatory while others may be user-defined.

**Generated Access File**

SEGNAME=SALES, CUBENAME=Sales, SCHEMA=, CATALOG=FoodMart 2000, 
DATASOURCE=TSCQ02, $
Reference: Selecting Valid Dimensions for a Measure

A data source view may have multiple fact tables as well as multiple dimension tables. Each fact table contains records for a specific set of measures called a *measure group*. A particular measure group may not have a relationship to every dimension table, and if you select a measure/dimension combination where there is no relationship, the returned data might be meaningless.

Starting in Version 7 Release 7.04, when you create a synonym, each measure group and its related dimensions are listed at the bottom of the synonym. In addition, the FIELD declaration each measure in the Master File has a MEASURE_GROUP attribute identifying the measure group to which it belongs. Using this information, the WebFOCUS tools will gray out the dimensions that are not valid for each measure group so that you can make a valid measure/dimension selection for your report.

For example, the following portion of the Adventure_Works Master File shows the Internet_Sales FIELD declaration with its MEASURE_GROUP attribute:

```plaintext
FIELDNAME=Internet_Sales_Amount, ALIAS='Internet Sales Amount',
USAGE=P12.2MB, ACTUAL=P8,
MISSING=ON,
TITLE='Internet Sales Amount', MEASURE_GROUP=Internet Sales,
PROPERTY=MEASURE, $
```

The following portion of the Adventure_Works Master File shows the Internet_Sales measure group along with the dimensions that are valid for this measure group:

```plaintext
MEASUREGROUP=Internet Sales, CAPTION='Internet Sales', $
  MEASGRPDIM=[Customer], $
  MEASGRPDIM=[Date], $
  MEASGRPDIM=[Delivery Date], $
  MEASGRPDIM=[Internet Sales Order Details], $
  MEASGRPDIM=[Product], $
  MEASGRPDIM=[Promotion], $
  MEASGRPDIM=[Sales Reason], $
  MEASGRPDIM=[Sales Territory], $
  MEASGRPDIM=[Ship Date], $
```
Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. Note: To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. Note: This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Reference:** **Access File Keywords**

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>CUBENAME</td>
<td>Name of the OLAP cube.</td>
</tr>
</tbody>
</table>
### Converting Alphanumeric Dates to WebFOCUS Dates

Microsoft Analysis Server (2005 through 2012) natively stores data (such as, member names and captions) in time dimensions in alphanumeric format without applying any particular standard, and it allows you to create members with names consisting of any combination of components such as year, quarter, and month, with any delimiter and in many languages. In a sorted report, if such data is sorted alphabetically, the sequence does not make business sense. To ensure adequate sorting, aggregation, and reporting on date fields, WebFOCUS converts the alphanumeric dates into standard WebFOCUS date format using a conversion pattern that you can specify in the Master File attribute called DATEPATTERN.

Each element in the pattern is either a constant character which must appear in the actual input or a variable that represents a date component. You must edit the USAGE attribute in the Master File so that it accounts for the date elements in the date pattern. The maximum length of the DATEPATTERN string is 64 characters.
Specifying Variables in a Date Pattern

How to:
Specify Years in a Date Pattern
Specify Month Names in a Date Pattern
Specify Days of the Month in a Date Pattern
Specify Julian Days in a Date Pattern
Specify Day of the Week in a Date Pattern
Specify Quarters in a Date Pattern

Reference:
Specify Month Numbers in a Date Pattern

The valid date components (variables) are year, quarter, month, day, and day of week. In the date pattern, variables are enclosed in square brackets (these brackets are not part of the input or output. Note that if the data contains brackets, you must use an escape character in the date pattern to distinguish the brackets in the data from the brackets used for enclosing variables).

Syntax: How to Specify Years in a Date Pattern

[YYYY]
   Specifies a 4-digit year.

[YY]
   Specifies a 2-digit year.

[yy]
   Specifies a zero-suppressed 2-digit year (For example, 8 for 2008).

[by]
   Specifies a blank-padded 2-digit year.

Reference: Specify Month Numbers in a Date Pattern

[MM]
   Specifies a 2-digit month number.
[

Specifies a zero-suppressed month number.

[bm]
Specifies a blank-padded month number.

**Syntax:** How to Specify Month Names in a Date Pattern

[MON]
Specifies a 3-character month name in uppercase.

[mon]
Specifies a 3-character month name in lowercase.

[Mon]
Specifies a 3-character month name in mixed-case.

[MOUTH]
Specifies a full month name in uppercase.

[month]
Specifies a full month name in lowercase.

[Month]
Specifies a full month name in mixed-case.

**Syntax:** How to Specify Days of the Month in a Date Pattern

[DD]
Specifies a 2-digit day of the month.

[dd]
Specifies a zero-suppressed day of the month.

[bd]
Specifies a blank-padded day of the month.

**Syntax:** How to Specify Julian Days in a Date Pattern

[DDD]
Specifies a 3-digit day of the year.
[ddd]
   Specifies a zero-suppressed day of the year.

[bdd]
   Specifies a blank-padded day of the year.

**Syntax:**  How to Specify Day of the Week in a Date Pattern

[WD]
   Specifies a 1-digit day of the week.

[DAY]
   Specifies a 3-character day name, uppercase.

[day]
   Specifies a 3-character day name, lowercase.

[Day]
   Specifies a 3-character day name, mixed-case.

[WDAY]
   Specifies a full day name, uppercase.

[wday]
   Specifies a full day name, lowercase.

[Wday]
   Specifies a full day name, mixed-case.

For the day of the week, the WEEKFIRST setting defines which day is day 1.

**Syntax:**  How to Specify Quarters in a Date Pattern

[Q]
   Specifies a 1-digit quarter number (1, 2, 3, or 4).

   For a string like Q2 or Q02, use constants before [Q], for example, Q0[Q].
Specifying Constants in a Date Pattern

**Example:**

<table>
<thead>
<tr>
<th>Sample Date Patterns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sorting By an Alphanumeric Date</td>
</tr>
<tr>
<td>Sorting By an Alphanumeric Date Containing Calendar Quarter</td>
</tr>
</tbody>
</table>

Between the variables, you can insert any constant values.

If you want to insert a character that would normally be interpreted as part of a variable, use the backslash character as an escape character. For example:

- Use `\[` to specify a left square bracket constant character.
- Use `\` to specify a backslash constant character.

For a single quotation mark, use two consecutive single quotation marks (`'`).

**Example:** Sample Date Patterns

If the date in the data source is of the form CY 2001 Q1, the DATEPATTERN attribute is:

```
DATEPATTERN = 'CY [YYYY] Q[Q]
```

If the date in the data source is of the form Jan 31, 01, the DATEPATTERN attribute is:

```
DATEPATTERN = '[Mon] [DD], [YY]
```

If the date in the data source is of the form APR-06, the DATEPATTERN attribute is:

```
DATEPATTERN = '[MON]-[YY]
```

If the date in the data source is of the form APR - 06, the DATEPATTERN attribute is:

```
DATEPATTERN = '[MON] - [YY]
```

If the date in the data source is of the form APR '06, the DATEPATTERN attribute is:

```
DATEPATTERN = '[MON] ''[YY]
```

If the date in the data source is of the form APR [06], the DATEPATTERN attribute is:

```
DATEPATTERN = '[MON] \[[YY]\]' (or '[MON] \[[YY]\]
```

Note the right square bracket does not have to be escaped.
**Example:** Sorting By an Alphanumeric Date

The following request against the Adventure Works cube sorts by the Month field:

```sql
TABLE FILE Adventure_works
SUM
Internet_Sales_Amount
BY Month
WHERE Calendar_Year EQ 'CY 2001' OR 'CY 2004'
ON TABLE SET PAGE-NUM OFF
ON TABLE NOTOTAL
ON TABLE SET HTMLCSS ON
END
```

The default synonym has the following declaration for the Month field:

```sql
FIELDNAME=Month, ALIAS=Month, USAGE=A14, ACTUAL=A14,
TITLE='Month',
WITHIN='Calendar_Quarter',
PROPERTY=CAPTION, $
```

The output shows that the months also have a year component and are sorted in alphabetical order, not month order:

<table>
<thead>
<tr>
<th>Month</th>
<th>Internet Sales Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>April 2004</td>
<td>$1,608,750.53</td>
</tr>
<tr>
<td>August 2001</td>
<td>$506,191.69</td>
</tr>
<tr>
<td>December 2001</td>
<td>$755,527.89</td>
</tr>
<tr>
<td>February 2004</td>
<td>$1,462,479.83</td>
</tr>
<tr>
<td>January 2004</td>
<td>$1,340,244.95</td>
</tr>
<tr>
<td>July 2001</td>
<td>$473,388.16</td>
</tr>
<tr>
<td>July 2004</td>
<td>$50,840.63</td>
</tr>
<tr>
<td>June 2004</td>
<td>$1,949,361.11</td>
</tr>
<tr>
<td>March 2004</td>
<td>$1,480,905.18</td>
</tr>
<tr>
<td>May 2004</td>
<td>$1,878,317.51</td>
</tr>
<tr>
<td>November 2001</td>
<td>$543,993.40</td>
</tr>
<tr>
<td>October 2001</td>
<td>$513,329.47</td>
</tr>
<tr>
<td>September 2001</td>
<td>$473,943.03</td>
</tr>
</tbody>
</table>
Now, make the following changes to the declaration for the Month field:

- Change the USAGE to a WebFOCUS date format with the same date components as the alphanumeric date (MtrYY).
- Add a DATEPATTERN attribute that describes the alphanumeric date stored in the field.
  - Variable: mixed case full month name, [Month].
  - Literal: blank space.
  - Variable: four-digit year, [YYYY].

```
FIELDNAME=Month, ALIAS=Month, USAGE=MtrYY, ACTUAL=A14,
    TITLE='Month',
    WITHIN='Calendar_Quarter',
    PROPERTY=CAPTION,
    DATEPATTERN = '[Month] [YYYY]',$
```

Re-running the request with these changes produces the following output in which the months are sorted correctly:

<table>
<thead>
<tr>
<th>Month</th>
<th>Internet Sales Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>July, 2001</td>
<td>$473,388.16</td>
</tr>
<tr>
<td>August, 2001</td>
<td>$506,191.69</td>
</tr>
<tr>
<td>September, 2001</td>
<td>$473,943.03</td>
</tr>
<tr>
<td>October, 2001</td>
<td>$513,329.47</td>
</tr>
<tr>
<td>November, 2001</td>
<td>$543,993.40</td>
</tr>
<tr>
<td>December, 2001</td>
<td>$755,527.89</td>
</tr>
<tr>
<td>January, 2004</td>
<td>$1,340,244.95</td>
</tr>
<tr>
<td>February, 2004</td>
<td>$1,462,479.83</td>
</tr>
<tr>
<td>March, 2004</td>
<td>$1,480,905.18</td>
</tr>
<tr>
<td>April, 2004</td>
<td>$1,608,750.53</td>
</tr>
<tr>
<td>May, 2004</td>
<td>$1,878,317.51</td>
</tr>
<tr>
<td>June, 2004</td>
<td>$1,949,361.11</td>
</tr>
<tr>
<td>July, 2004</td>
<td>$50,840.63</td>
</tr>
</tbody>
</table>
Example: Sorting By an Alphanumeric Date Containing Calendar Quarter

The following request against the Adventure Works cube sorts by the Calendar_Quarter field:

```sql
TABLE FILE Adventure_works
SUM
Internet_Sales_Amount
BY Calendar_Quarter
WHERE Calendar_Year EQ 'CY 2001' OR 'CY 2004'
ON TABLE SET PAGE-NUM OFF
ON TABLE NOTOTAL
ON TABLE SET HTMLCSS ON
END
```

The default synonym has the following declaration for the Calendar_Quarter field:

```sql
FIELDNAME=Calendar_Quarter, ALIAS='Calendar Quarter', USAGE=A10, ACTUAL=A10, TITLE='Calendar Quarter', WITHIN='Calendar_Semester', PROPERTY=CAPTION,$
```

The output shows that the quarters are sorted in alphabetical order, not quarter and year order:

<table>
<thead>
<tr>
<th>Calendar Quarter</th>
<th>Internet Sales Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q1 CY 2004</td>
<td>$4,283,629.96</td>
</tr>
<tr>
<td>Q2 CY 2004</td>
<td>$5,436,429.15</td>
</tr>
<tr>
<td>Q3 CY 2001</td>
<td>$1,453,522.88</td>
</tr>
<tr>
<td>Q3 CY 2004</td>
<td>$50,840.63</td>
</tr>
<tr>
<td>Q4 CY 2001</td>
<td>$1,812,850.77</td>
</tr>
</tbody>
</table>

Now, make the following changes to the declaration for the Calendar_Quarter field:

- Change the USAGE to a WebFOCUS date format containing the quarter and year (QYY).
- Add a DATEPATTERN attribute that describes the alphanumeric date stored in the field:
  - Literal value, Q: Q
  - Variable Quarter: [Q]
  - Literal value, space followed by CY followed by space: CY
Variable four-digit year: [YYYY]

FIELDNAME=Calendar_Quarter, ALIAS='Calendar Quarter', USAGE=QYY,
ACTUAL=A10,
TITLE='Calendar Quarter',
WITHIN='Calendar_Semester',
PROPERTY=CAPTION,
DATEPATTERN = 'Q[Q] CY [YYYY]',$

Re-running the request with these changes produces the following output in which the quarters are sorted correctly. Note that the displayed value uses the WebFOCUS date format, not the original alphanumeric date format:

<table>
<thead>
<tr>
<th>Calendar Quarter</th>
<th>Internet Sales Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q3 2001</td>
<td>$1,453,522.88</td>
</tr>
<tr>
<td>Q4 2001</td>
<td>$1,812,850.77</td>
</tr>
<tr>
<td>Q1 2004</td>
<td>$4,283,629.96</td>
</tr>
<tr>
<td>Q2 2004</td>
<td>$5,436,429.15</td>
</tr>
<tr>
<td>Q3 2004</td>
<td>$50,840.63</td>
</tr>
</tbody>
</table>

Customizing the SQL Server Analysis Services Environment

**In this section:**

- Specifying a Timeout Limit
- Activating NONBLOCK Mode and Issuing a TIMEOUT Limit
- Retrieving Rows (Report Lines) Without Values
- Including System Hierarchies in Synonyms
- Using the MDX VISUALTOTALS Function
- Redirecting UDA References to Attribute Hierarchies
- Accelerating Queries
- Adapter Functionality

The Adapter for SQL Server Analysis Services provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.
Tip: You can change this setting from the Web Console by clicking Data Adapters in the navigation pane, clicking the name of a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Specifying a Timeout Limit

**How to:**
Specify a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after it issues a request to SQL Server Analysis Services.

**Syntax:**
How to Specify a Timeout Limit

ENGINE SSAS SET COMMANDTIMEOUT \{nn\} \{0\}
where:

\*nn\*
Is the number of seconds before a timeout occurs. 30 is the default value.

\*0\*
Represents an infinite period to wait for response.

**Note:** If you do not specify a COMMANDTIMEOUT value, the current SQL Server Analysis Services default timeout setting is used.

Activating NONBLOCK Mode and Issuing a TIMEOUT Limit

**How to:**
Activate NONBLOCK Mode and Issue a TIMEOUT Limit

You can use the NONBLOCK command to prevent runaway queries. The Adapter for SQL Server Analysis Services uses non-blocking protocol for query execution.

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to SQL Server Analysis Services.

**Syntax:**
How to Activate NONBLOCK Mode and Issue a TIMEOUT Limit

ENGINE SSAS SET NONBLOCK \( n \) \{TIMEOUT \( m \)\)
where:

\( n \)

Is the polling period in seconds.

\( m \)

Is the total timeout after which the query is terminated if it does not get completed.

## Retrieving Rows (Report Lines) Without Values

### How to:

Control EMPTY Mode

### Example:

Activating EMPTY Mode

You can use the `SET EMPTY` command to display or suppress rows, or report lines, where all the selected measure columns have empty values.

### Syntax: How to Control EMPTY Mode

```
ENGINE SSAS SET EMPTY {ON|OFF}
```

where:

ON

Does not suppress rows, or report lines, without values.

OFF

Suppresses rows, or report lines, without values. This is the default.

### Example: Activating EMPTY Mode

In the following request, EMPTY is set to OFF. Therefore, rows (report lines) with no data are suppressed.

```
TABLE FILE SALES
PRINT Profit
BY City
END
```
The partial output is:

<table>
<thead>
<tr>
<th>City</th>
<th>Profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Albany</td>
<td>8,516.532900000</td>
</tr>
<tr>
<td>Altadena</td>
<td>3,345.876900000</td>
</tr>
<tr>
<td>Anacortes</td>
<td>956.535100000</td>
</tr>
</tbody>
</table>

With EMPTY set to ON, the rows (report lines) with no data are displayed.

<table>
<thead>
<tr>
<th>City</th>
<th>Profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acapulco</td>
<td>.</td>
</tr>
<tr>
<td>Albany</td>
<td>8,516.532900000</td>
</tr>
<tr>
<td>Altadena</td>
<td>3,345.876900000</td>
</tr>
<tr>
<td>Anacortes</td>
<td>956.535100000</td>
</tr>
</tbody>
</table>

### Including System Hierarchies in Synonyms

#### How to:
Include System Hierarchies in Synonyms

Some hierarchies are flagged as user-defined. By default, synonyms include fields only for user-defined hierarchies. To create synonyms that include fields for all hierarchies in a cube, issue the `ENGINE SSAS SET SYSTEMHIERACHIES` command in any supported profile.

You can also select this option when creating a synonym by checking the `Include System-Enabled Hierarchies` check box.

**Note:** You can redirect UDA references to attribute hierarchies without including them in the synonym using the `SET USE_ATTRIBUTE_HIERARCHIES` command. For more information, see *Redirecting UDA References to Attribute Hierarchies* on page 2335.

#### Syntax: How to Include System Hierarchies in Synonyms

```
ENGINE SSAS SET SYSTEMHIERACHIES {ON | OFF}
```

where:

- **ON**
  - Includes fields for all hierarchies when creating a synonym.

- **OFF**
  - Includes fields only for those hierarchies flagged as user-defined when creating a synonym. OFF is the default value.
Using the MDX VISUALTOTALS Function

**How to:**

- Change the Default ROLLUP_BY_VISUALTOTALS Setting
- Change the ROLLUP_BY_VISUALTOTALS Setting for All Hierarchies in a Synonym
- Change the ROLLUP_BY_VISUALTOTALS Setting for All Hierarchies Within a Dimension
- Change the ROLLUP_BY_VISUALTOTALS Setting for a Hierarchy
- Enable Rollup by Visual Totals in a Profile or FOCEXEC
- Query SSAS Adapter Settings

To retrieve data from a SSAS cube, the adapter translates the WebFOCUS request to MDX, the language that is used by the SSAS engine. SSAS then returns the cells containing values of the selected measures for the specified members.

The values stored in the cube are aggregates resulting from rolling up measures along the cube dimensions when the cube was processed, and are based on rolling up all the underlying members of the hierarchy. Some reports perform selections on hierarchy levels below the levels selected for display. For example:

```
TABLE FILE ADVENTURE_WORKS
WRITE INTERNET_SALES_AMOUNT
BY COUNTRY
WHERE STATE_PROVINCE EQ 'California' OR 'New York'
END
```

The resulting report will display the value of the *Internet Sales Amount* measure for the hierarchy member *United States*. There are two possible approaches to what is the correct value to show:

1. Show the value for the hierarchy member *United States* as it exists in the cube (having been rolled up from values of all the underlying members). This is called a *full rollup*.

2. Show the value for the hierarchy member *United States* rolled up based on *California* and *New York* only. This is called a *visual total*.

By default, the adapter uses option 2 and displays visual totals. To produce the proper result based on the report selection criteria such as WHERE/IF clauses for level hierarchies, or WHEN clauses for parent/child hierarchies (with account for measure calculations, custom member rollups, etc.), the adapter uses the MDX VISUALTOTALS function, thus delegating the rollup to the SSAS engine.
When this option is in effect, the displayed values are determined by the report selection criteria and dimension levels referenced in the sort phrases (BY and ACROSS) for level hierarchies, or explicit member selection for Parent/Child hierarchies and dimensions not referenced by sort phrases.

The type of rollup to perform is controlled by the adapter parameter setting ROLLUP_BY_VISUALTOTALS. You can change the default value using the Change Settings panel in the Web Console. For information, see How to Change the Default ROLLUP_BY_VISUALTOTALS Setting on page 2330.

In the Synonym Editor, you can set a ROLLUP_BY_VISUALTOTALS value for:

- All hierarchies within all dimensions in a selected synonym. For information, see How to Change the ROLLUP_BY_VISUALTOTALS Setting for All Hierarchies in a Synonym on page 2331.
- All hierarchies within selected dimensions in a selected synonym. For information, see How to Change the ROLLUP_BY_VISUALTOTALS Setting for All Hierarchies Within a Dimension on page 2332.
- Specific hierarchies within selected dimensions in a selected synonym. For information, see How to Change the ROLLUP_BY_VISUALTOTALS Setting for a Hierarchy on page 2334.

**Syntax:** How to Enable Rollup by Visual Totals in a Profile or FOCEXEC

Visual Totals mode is enabled by the following setting that can be issued in a FOCEXEC or a server or user profile.

ENGINE SSAS SET ROLLUP_BY_VISUALTOTALS {ON | OFF}

where:

**ON**

Uses the MDX VISUALTOTALS function to recalculate measure values so that, on the report output, they reflect only those members selected in the report request. ON is the default value.

**OFF**

Retrieves values stored in the cube without having them recalculated based on the member selections in the report request.

**Procedure:** How to Change the Default ROLLUP_BY_VISUALTOTALS Setting

By default, the MDX VISUAL TOTALS function is enabled. To change the default:

1. Click Adapters on the menu bar.
2. Right-click the adapter name and select Change Settings from the context menu.
3. Select ON or OFF from the ROLLUP_BY_VISUALTOTALS drop-down list:
4. Click Save.

The setting is saved in the server profile, edasprof.prf.

Procedure: How to Change the ROLLUP_BY_VISUALTOTALS Setting for All Hierarchies in a Synonym

Before you make any changes, all hierarchies within all synonyms inherit the default ROLLUP_BY_VISUALTOTALS value set in the server profile.

1. Open the synonym in the Synonym Editor.
2. Right-click the dimensions folder and mouse over Rollup by VisualTotals from the context menu.
3. Select one of the following options:

- **Default**, which inherits the value from the value set in the server profile.
- **On**, which turns ROLLUP_BY_VISUALTOTALS ON for all hierarchies in all dimensions. You can then change the value for specific dimensions or for specific hierarchies.
- **Off**, which turns ROLLUP_BY_VISUALTOTALS OFF for all hierarchies in all dimensions. You can then change the value for specific dimensions or for specific hierarchies.

**Procedure:** How to Change the ROLLUP_BY_VISUALTOTALS Setting for All Hierarchies Within a Dimension

Before you make any changes, all hierarchies within all dimensions inherit the ROLLUP_BY_VISUALTOTALS value set for the synonym (which may have been the default setting inherited from the server profile).

1. Open the synonym in the Synonym Editor.
2. Right-click the dimension name and mouse over Rollup by VisualTotals from the context menu.
3. Select one of the following options:

- **Default**, which inherits the value from the value set for the synonym.
- **On**, which turns ROLLUP_BY_VISUALTOTALS ON for all hierarchies in that dimension. You can then change the value for specific hierarchies.
- **Off**, which turns ROLLUP_BY_VISUALTOTALS OFF for all hierarchies in that dimension. You can then change the value for specific hierarchies.

**Procedure:** How to Change the ROLLUP_BY_VISUALTOTALS Setting for a Hierarchy

Before you make any changes, all hierarchies within a dimension inherit the default ROLLUP_BY_VISUALTOTALS value set for the dimension (which may be the value inherited from the synonym).

1. Open the synonym in the Synonym Editor.
2. Right-click the hierarchy name and mouse over *Rollup by VisualTotals* from the context menu.

3. Select one of the following options:
   - **Default**, which inherits the value from the value for the dimension.
   - **On**, which turns ROLLUP_BY_VISUALTOTALS ON for that hierarchy in that dimension.
- **Off**, which turns ROLLUP_BY_VISUALTOTALS OFF for that hierarchy in that dimension.

**Syntax:**  
**How to Query SSAS Adapter Settings**

The following command displays all settings in effect at the time it is issued.

```
ENGINE SSAS ?
```

For example:

- (FOC11351) EXCLUSION OF EMPTY CELLS FROM REPORT - ON
- (FOC11350) CROSSJOIN OPTIMIZATION - ON
- (FOC11352) NONBLOCK OPTION - OFF, POLLING INTERVAL - N/A, TIMEOUT - default
- (FOC11366) USE ATTRIBUTE HIERARCHIES - OFF
- (FOC11369) DEFAULT FOR ROLLUP_BY_VISUALTOTALS - ON

**Redirecting UDA References to Attribute Hierarchies**

**How to:**
Redirect UDA References to Attribute Hierarchies

**Example:**
Effect of Redirecting UDA References to Attribute Hierarchies

UDAs (User-Defined Attributes) are Properties that are represented by Master File fields with the attribute PROPERTY=ATTRIBUTE. They correspond to SSAS metadata entities defined in the MDSCHEMA_PROPERTIES Rowset for hierarchies and their levels. In the Business Management Studio, these entities are created as Attribute Relationships that link attributes comprising hierarchy levels to other related attributes. Examples of such properties/attribute relationships could be Color and Net Weight for Product, or Address, Phone Number and Gender for Customer.

By default, SSAS creates a separate attribute hierarchy for each dimension attribute. The members of these hierarchies contain aggregated values for distinct values of the attribute. Some of these aggregations might or might not have business sense. For example, aggregation of Sales Amount by customer gender might make sense, while aggregation by phone number does not.

Within the current implementation of the SSAS Adapter, a BY clause determines the level at which aggregated data is extracted from a cube. Therefore, if COLOR is a field referencing the Color UDA, the BY COLOR clause causes individual members of the Product hierarchy level to be extracted. It is equivalent to BY COLOR BY PRODUCT NOPRINT.

To see values aggregated by Color, you can reference the Master File field that was created for the corresponding level of the Color attribute hierarchy. However, this might be inconvenient for the following reasons:
By default, attribute hierarchies are not included in a Master File. If you want them to be included, you must click the *Include System-Enabled Hierarchies* check box at synonym creation time.

If, at synonym creation time, the user requests inclusion of attribute hierarchies, the Master File can become very large and difficult to present visually.

There is no visual link between a hierarchy level and the related attribute hierarchies.

If you issue the adapter `SET USE_ATTRIBUTE_HIERARCHIES ON` command, the adapter automatically interprets references to UDA fields as references to the corresponding attribute hierarchies. Therefore, although the attribute hierarchies are not included in the Master File, the adapter will use them to retrieve the aggregated measure values when a request references the UDA resulting from the attribute relationship created for this attribute.

### Syntax: How to Redirect UDA References to Attribute Hierarchies

```sql
ENGINE SSAS SET USE_ATTRIBUTE_HIERARCHIES {ON | OFF}
```

where:

- **ON** redirects UDA references to corresponding attribute hierarchies.
- **OFF** does not redirect UDA references to attribute hierarchies. OFF is the default value.

**Note:** This setting applies only to Master Files created with level hierarchies.

### Example: Effect of Redirecting UDA References to Attribute Hierarchies

In the Adventure_Works Master File, the Product dimension has a level named Product with a user-defined attribute (UDA) named Color. The following request sums Internet Sales Amount by Subcategory and Color. It does not mention Product:

```sql
TABLE FILE ADVENTURE_WORKS
WRITE INTERNET_SALES_AMOUNT
BY SUBCATEGORY1
BY COLOR
WHERE SUBCATEGORY1 LIKE 'S'
END
```
The setting USE_ATTRIBUTE_HIERARCHIES OFF (which is the default), results in the following report in which the values by Color are not aggregated along Product. A separate line is generated for each product (to see the product names, add a BY PRODUCT phrase after the BY COLOR phrase):

<table>
<thead>
<tr>
<th>Subcategory</th>
<th>Color</th>
<th>Internet Sales Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shorts</td>
<td>Black</td>
<td>$21,276.96</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$24,636.48</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$25,406.37</td>
</tr>
<tr>
<td>Socks</td>
<td>White</td>
<td>$2,679.02</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$2,427.30</td>
</tr>
</tbody>
</table>

However, the setting ENGINE SSAS SET USE_ATTRIBUTE_HIERARCHIES ON results in the following report in which the values for Color are automatically aggregated by Product:

<table>
<thead>
<tr>
<th>Subcategory</th>
<th>Color</th>
<th>Internet Sales Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shorts</td>
<td>Black</td>
<td>$71,319.81</td>
</tr>
<tr>
<td>Socks</td>
<td>White</td>
<td>$5,106.32</td>
</tr>
</tbody>
</table>

### Accelerating Queries

**How to:**

Accelerate Query Performance Using CROSSJOINOPTIMIZATION

**Example:**

Accelerating Query Performance Using CROSSJOINOPTIMIZATION

Combining EMPTY OFF With CROSSJOINOPTIMIZATION NONEMPTY

The Adapter for SQL Server Analysis Services (SSAS) supports a number of modes of operation for accelerating the performance of queries that deal with large volumes of data, particularly those that require instantiation of large numbers of cells. Since the number of cells resulting from the query is equal to the product of cardinalities of member sets selected for each of the referenced dimensions, a very large number of cells can be involved.

These options may speed up or, under some circumstances, slow down particular queries. Since it is difficult to predict which approach will be most effective in a particular situation, it is useful to try various combinations of options for queries with slow response times to determine which produces the best performance results.
Syntax: **How to Accelerate Query Performance Using CROSSJOINOPTIMIZATION**

Used in conjunction with the SET EMPTY OFF command, the CROSSJOINOPTIMIZATION command usually significantly accelerates queries that involve two or more large dimensions. The syntax is

\[
\text{ENGINE SSAS SET CROSSJOINOPTIMIZATION \{ON|OFF|NONEMPTY\}}
\]

where:

**ON**

Optimizes queries by generating a MDX statement with CROSSJOINs of the sets of members of referenced dimensions on the ROWS axis instead of generating an MDX statement with each dimension on a separate axis. ON is the default value.

When SET EMPTY is OFF (the default), this technique reduces the amount of data passed from the SQL Analysis Services client to the adapter by delegating the screening of empty tuples of data to the Analysis Services engine. The reduction is especially dramatic when low dimension levels on many dimensions are involved. (If EMPTY is ON, this option will not reduce the amount of data passed from the client to the adapter.)

**OFF**

Suppresses CROSSJOIN optimization. This is provided for performance comparison and tuning purposes.

**NONEMPTY**

Optimizes queries by generating an MDX statement with NONEMPTYCROSSJOINs of the sets of referenced dimensions on the ROWS axis.

**Note:** The SET EMPTY command must be set to OFF (the default), to use this option.

Under certain conditions, the NONEMPTY option delivers the best performance for queries that reference low levels of multiple dimensions because these queries usually yield very high numbers of cells. However, NONEMPTYCROSSJOINs cannot be used if the dimensions contain calculated members. In such cases the resulting reports will be incorrect. (If this occurs, try the CROSSJOINOPTIMIZATION ON.)

Before using this option, refer to the description of the NONEMPTYCROSSJOIN function in the Microsoft Analysis Services documentation.

**Tip:** You can change this setting from the Web Console by clicking *Data Adapters* in the navigation pane, clicking the name of a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.
Example: Accelerating Query Performance Using CROSSJOINOPTIMIZATION

Suppose that you want to create an intermediate file containing the data aggregated on the lowest levels for the dimensions TIME, PRODUCT, CUSTOMER and STORE:

```
TABLE FILE SALES
  SUM Sales_Count Store_Sales Store_Cost Unit_Sales
  BY Month
  BY Name
  BY Store_Name
  BY Product_Name
  ON TABLE HOLD
END
```

Given the cardinalities of the involved levels: (24, 10281, 25 and 1560, correspondingly) this request would never be completed without CROSSJOIN optimization because Microsoft Analysis Services software would have to instantiate an astronomical number of cells: 9623016000. However, if you set CROSSJOINOPTIMIZATION to NONEMPTY the request finishes within 30 seconds, resulting in a HOLD file that contains 250983 records.

Example: Combining EMPTY OFF With CROSSJOINOPTIMIZATION NONEMPTY

The SET EMPTY OFF command suppresses rows, or report lines, where all the selected measure columns have empty values. For example, in the following request,

```
TABLE FILE SALES
  SUM Sales_Count Store_Sales Store_Cost Unit_Sales
  BY Month
  BY Name
  BY Store_Name
END
```

most users would prefer to see on the report only those combinations of stores and customers where Unit_Sales contains a number reflecting actual sales (EMPTY OFF), rather than seeing all possible combinations of stores and customers where the majority of report lines probably contain a 0 or a dot in the Unit_Sales column (EMPTY ON).

In EMPTY OFF mode, CROSSJOIN optimization delegates the selection of the non-empty rows to the database engine.

Adapter Functionality

Example: Using SUM and PRINT Commands in a Report Request

The Adapter for SQL Server Analysis Services (SSAS) supports:
JOIN commands. The Adapter for SQL Server Analysis Services (SSAS) does not support direct JOINs from or to a cube. Therefore, SQL JOINs using WHERE criteria are not supported. To achieve a joined request, use the FOCUS MATCH FILE command or create a HOLD file and include the HOLD file in the joined request.

SUM and PRINT commands with Measures dimensions. When using these commands in a request, the verb used against the Adapter for SQL Server Analysis Services (SSAS) does not affect the output, which is always the value found in the cube.

Example: Using SUM and PRINT Commands in a Report Request

In the following request, the PRINT verb is used, and SUM is the aggregator for STORE_COSTS. However, the value displayed is always the value stored in the cube or the specified measure at the intersection of the dimension values, regardless of the verb used in the request.

```
TABLE FILE SALES
PRINT Store_Costs
BY City
END
```

The correct request produces the same report output:

```
TABLE FILE SALES
SUM Store_Costs
BY City
END
```

The partial output is:

<table>
<thead>
<tr>
<th>City</th>
<th>Store Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>Albany</td>
<td>5,593.28</td>
</tr>
<tr>
<td>Altadena</td>
<td>2,239.71</td>
</tr>
<tr>
<td>Anacortes</td>
<td>641.93</td>
</tr>
<tr>
<td>Arcadia</td>
<td>2,045.73</td>
</tr>
<tr>
<td>Ballard</td>
<td>2,169.51</td>
</tr>
</tbody>
</table>
SQL Server Analysis Services (SSAS) Reporting With WebFOCUS

Two types of hierarchy are represented in a synonym: level and parent/child:

- A synonym describes a level hierarchy by using a separate field for each level. To report on a level hierarchy, you use columnar reporting in which you specify the field name for each level you want to display as a BY field in the request.

- A synonym describes a parent/child hierarchy using a set of fields that define the hierarchical structure and the relationships between the hierarchy members. The adapter has special hierarchical reporting syntax for reporting on parent/child hierarchies.

Overview of Reporting Concepts

In a multi-dimensional data source (cube), dimensions are categories of data, such as Region or Time, that you use to analyze and compare business performance. Dimensions consist of data elements that are called members. For example, a Region dimension could have members England and France.

Dimension members are usually organized into hierarchies. Hierarchies can be viewed as tree-like graphs where members are the nodes.

For example, the Region dimension may have the element World at its top level (the root node). The World element may have children nodes (members) representing continents. Continents, in turn, can have children nodes that represent countries, and countries can have children nodes representing states or cities. Nodes with no children are called leaf nodes.

Measures are numeric values, such as Sales Volume or Net Income, that are used to quantify how your business is performing.
A multi-dimensional cube consists of data derived from facts, which are records about individual business transactions. For example, an individual fact record reflects a sales transaction of a certain number of items of a certain product at a certain price, which occurred in a certain store at a certain moment of time. The cube contains summarized fact values for all combinations of measures and members of different dimensions.

For example, the following combination (tuple) contains the total volume of sales of pumps in all stores in England in 2005:

\{Sales Volume, Pumps, England, 2005\}

The point in the cube that contains this summarized value is called a cell. A cell is addressed by a combination of members of different dimensions and a measure. In this example Sales Volume is a measure and Pumps, England, and 2005 are members of the Product, Region, and Time dimensions respectively.

Individual fact records are usually tied to the leaf nodes of each hierarchy in the cube. The fact values get included in cells addressed by these leaf nodes and added to all cells addressed by all combinations of ascendants of these leaf nodes along each hierarchy of the cube.

The operation used to summarize facts for some measures can be a simple sum or a more complex aggregation function such as an average.

Some combinations of hierarchy nodes may not have any fact records tied to them. The cells addressed by these combinations are empty cells.

As illustrated in the previous example, a tuple is a combination of members from different dimensions of a cube. The previous tuple contains members from all dimensions and, therefore, addresses a single cell. If a tuple contains only members from some dimensions, it addresses not just one cell but a whole slice of cells in the cube. For example, the following tuple does not include either Region or Time dimension members:

\{Sales Volume, Pumps\}

It addresses as many cells in the cube as there are members of the Region dimension times the number of members of the Time dimension.

The number of cells in the cube addressed by a single dimension member is a product of cardinalities of all other dimensions.

When all cells addressed by a member are empty, the member is called an empty member. When all cells addressed by a tuple are empty, the tuple is called an empty tuple.

By default, empty cells do not appear on report output. You can issue the following command if you want them on the report output:

ENGINE SSAS SET EMPTY ON
OLE DB for OLAP (ODBO) defines three basic types of hierarchy structures: balanced, unbalanced, and ragged.

- In balanced hierarchies, all leaf members belong to the lowest hierarchy level. If a hierarchy member has a parent, the parent is exactly one level above the member.

- In unbalanced hierarchies, not all leaf members belong to the lowest level of the hierarchy.

- In ragged hierarchies, some members have their immediate parents (children) more than one level above (below) them.

The SSAS implementation of OLAP introduces its own terminology. SSAS hierarchies can be standard or parent-child. This characteristic has more to do with the way the hierarchy is defined rather than with its actual structure. Standard hierarchies are created from relational tables in such a way that each level of the hierarchy corresponds to a column in a relational table (of a column-based expression). Parent-child hierarchies, however, are created from tables having two essential columns. One containing the unique identifier of a member and another containing the identifier of its parent.

Thus, for standard hierarchies, the number of levels is fixed at the time when the hierarchy is defined. For parent-child hierarchies, the number of levels is determined by the contents of tables from which they are created rather than their columnar structure. Therefore, this number may change each time the hierarchy is loaded.

Usually, names of levels of standard hierarchies are inherited from the names of the corresponding relational columns because the data in different columns of a relational table are organized according to its semantics. Data items with the same semantics belong to the same column (for example country names belong to the Country column, city names belong to the City column). Level names of parent-child hierarchies are either automatically generated or assigned by the OLAP administrator, depending on the nature of the hierarchy data because data items in parent-child tables tend to be homogeneous. A list of company employees is a typical example of data that is naturally organized this way.

At the time of creation of a standard hierarchy it is possible to specify the convention for missing members. For example, a NULL value might represent a missing member. For example, a NULL value in the State column in a row of the Geography table containing values 'USA'-NULL-'Washington DC' means that the Washington DC member's parent is USA, which is two levels above it. This mechanism allows creation of standard hierarchies which, from the ODBO point of view, have unbalanced and/or ragged structures.

For parent-child hierarchies, SSAS currently does not provide an option for specifying a missing member. Thus it is currently impossible to create a parent-child hierarchy with a ragged structure. However, parent-child hierarchies typically (but not necessarily) have an unbalanced structure.

This difference between standard and parent-child hierarchies also explains why different levels of a standard hierarchy usually have different sets of user-defined properties, while all levels of a parent-child hierarchy have identical sets of user-defined properties.
When the adapter accesses a multi-dimensional cube, it uses two types of metadata elements about dimensions:

- **Hierarchy fields.** These fields contain data that apply to a specific hierarchy and describe each member position within that hierarchy. For example, these fields identify the member parent as well as its own name, caption, and unique ID.

- **Dimension properties.** These fields contain data that potentially apply to all members of the dimension. For example, a Region dimension may have a property called GEOGRAPHICAL_HEIGHT that specifies the altitude for each member of the Region dimension.

Using the hierarchy fields, the adapter can recreate the hierarchy and locate portions of the hierarchy needed to satisfy a request.

**Understanding Columnar and Hierarchical Reporting**

**Reference:**

Prerequisites for Hierarchical Reporting

Hierarchical reporting enables you to sort and select members of parent/child hierarchies without knowing specific level numbers.

A hierarchical reporting request goes through several phases before output is displayed.

**Hierarchical Sorting and Member Selection**

The first phase selects hierarchy members to display. The hierarchical reporting phrase BY or ON HIERARCHY automatically sorts and formats a hierarchy with appropriate indentations that show the parent/child relationships. If you do not want to see the entire hierarchy, you can use the WHEN phrase to select hierarchy members for display. The expression in this WHEN phrase must reference only hierarchy fields, not dimension properties or measures.

Measures cannot be used in selecting hierarchy levels for display.

**Screening Dimension Data**

Members are selected using the WHEN phrase. WHERE and IF phrases are not supported.

**Screening Based on Aggregated Values**

Measures, being summarized values, can be referenced in WHERE TOTAL tests and COMPUTE commands because those commands are processed after the hierarchy selection and aggregation phases of the request. When screening with WHERE TOTAL, the aggregation phase of the report processing is over, so totals on the report are not recalculated to account for the data that is screened out, the rows are just removed.
**Reference:** Prerequisites for Hierarchical Reporting

Hierarchical reporting uses special metadata attributes and reporting syntax. You must:

- Create a synonym that describes hierarchies as parent/child relationships.
- Use hierarchical reporting syntax in your request to automatically build and format hierarchies in the report output.

**Representing Hierarchies in a Synonym**

**Example:**

<table>
<thead>
<tr>
<th>Dimension Declaration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Describing a Level Hierarchy</td>
</tr>
<tr>
<td>Describing a Parent/Child Hierarchy</td>
</tr>
<tr>
<td>Dimension Properties</td>
</tr>
<tr>
<td>Sample Request Using a Level Hierarchy</td>
</tr>
<tr>
<td>Sample Request Using a Parent/Child Hierarchy</td>
</tr>
</tbody>
</table>

Dimensions are organized into sets of hierarchies. For example, in a Time dimension, years, quarters, and months can form a hierarchical or parent/child relationship. This means that the measures for each month are aggregated into values for quarters, and the quarters are aggregated into values for years. Each point in the hierarchy is called a **node**. Nodes at the bottom of the hierarchy (with no children) are called **leaf nodes**.

In a synonym, hierarchies can be described in one of two ways:

- **Level hierarchy.** Each hierarchy level is described using a separate field name. To issue a report request, you must reference the field name for those levels you want to display on the report output.

  When you create a synonym, the synonym contains one field declaration for each level. This declaration also specifies which field is its parent. If the data changes to have an additional level, you must recreate the synonym in order to account for this additional field and parent reference.

- **Parent/child hierarchy.** The hierarchy is described with a set of fields that contain values for properties that describe each member position in the hierarchy. For example, there are fields to contain a member unique ID, parent, and caption. To issue a report request, you only need to specify the field name of one of the hierarchy fields.

  With a parent/child hierarchy, one set of field names in the synonym describes the hierarchy. A change in the number of levels does not require a change to the synonym.
Another advantage of parent/child hierarchies is that the adapter can recreate and format any portion of the hierarchy. The request does not have to specify levelNumbers.

Dimension properties apply to all hierarchies in the dimension and are listed in the synonym following all of the hierarchies.

**Example:** **Dimension Declaration**

Each dimension begins with a dimension record that defines the dimension and its hierarchies. The dimension itself is level zero.

Dimension:

```
DIMENSION=[Employee], CAPTION='Employee', $
```

**Example:** **Describing a Level Hierarchy**

Each level of the hierarchy is assigned a field name consisting of the hierarchy name with the level number appended. Each field declaration also specifies the field name of its parent with the WITHIN attribute. The value stored in this field is the member caption (title).

If a new level appears in the data, the synonym must be recreated to define this new level.

The following field describes level three. Its parent is level 2:

```
FIELDNAME=Product_Category, ALIAS='Product Category', USAGE=A20, ACTUAL=A20, TITLE='Product Category', WITHIN='Product_Department', PROPERTY=CAPTION, $
```

**Example:** **Describing a Parent/Child Hierarchy**

Several fields are used to define a parent/child hierarchy. Each has a PROPERTY attribute that describes which hierarchy property it represents. The hierarchy field names are formed by appending a suffix to the hierarchy name.

For example, the caption of a hierarchy named Departments is stored in a field whose name is Departments and whose property attribute is PROPERTY=CAPTION.

The following table describes the hierarchy fields:

<table>
<thead>
<tr>
<th>Description of Data</th>
<th>PROPERTY=</th>
<th>Field Suffix</th>
</tr>
</thead>
<tbody>
<tr>
<td>Member's Unique ID (unique within the cube)</td>
<td>UID</td>
<td></td>
</tr>
<tr>
<td>Description of Data</td>
<td>PROPERTY=</td>
<td>Field Suffix</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Member’s Name (unique within the hierarchy)</td>
<td>NAME</td>
<td>_name</td>
</tr>
<tr>
<td>Member’s Level Number</td>
<td>LEVEL_NUMBER</td>
<td>_lvno</td>
</tr>
<tr>
<td>Member’s Parent</td>
<td>PARENT_OF</td>
<td>_parent</td>
</tr>
<tr>
<td>Parent’s Level Number</td>
<td>PARENT_LEVEL_NUMBER</td>
<td>_parent_lvno</td>
</tr>
<tr>
<td>Number of Children</td>
<td>CHILDREN_CARDINALITY</td>
<td>_children_card</td>
</tr>
<tr>
<td>Member’s Caption (title on reports)</td>
<td>CAPTION</td>
<td>_caption</td>
</tr>
</tbody>
</table>

The following declaration for the Departments hierarchy describes the field that contains a member’s unique ID (PROPERTY=UID):

```sql
FIELDNAME=Departments, USAGE=A143, ACTUAL=A143, MISSING=ON,
    TITLE='Departments Member Unique Name',
    WITHIN='*[Department].[Departments]',
    REFERENCE=[Department], PROPERTY=UID, $
```

The following declaration for the Departments hierarchy defines the field that contains a member’s title (PROPERTY=CAPTION):

```sql
FIELDNAME=Departments_caption, USAGE=A60, ACTUAL=A60, MISSING=ON,
    TITLE='Departments Member Caption',
    REFERENCE=ADVENTURE_WORKS.Departments, PROPERTY=CAPTION
```

**Example:** **Dimension Properties**

Following all hierarchies, the dimension properties (called *attributes*) are described. Each of these has PROPERTY=ATTRIBUTE in the synonym.

For example, the following field represents the property *occupation* in the Customers hierarchy:

```sql
FIELDNAME=Occupation, ALIAS=Occupation, USAGE=A14, ACTUAL=A14, MISSING=ON,
    TITLE='Occupation',
    REFERENCE=Customer, PROPERTY=ATTRIBUTE, $
```
**Example:** Sample Request Using a Level Hierarchy

A report request against a level hierarchy must specify the field name for each level of the hierarchy required in the report.

For example, the following request displays the Profit measure for levels 1 through 3 of the Customers hierarchy:

```plaintext
TABLE FILE baseapp/sales
SUM
  Profit
  BY Country AS 'Level1'
  BY StateProvince AS 'Level2'
  BY City AS 'Level3'
END
```

The partial output is:

```
Level1  Level2  Level3          Profit  
USA     CA      Altadena  3,345.87690000000
Arcadia 3,090.86140000000
Bellflower 3,995.49900000001
```

In order to get a total for the entire hierarchy, you have to use an ON TABLE COLUMN-TOTAL command in the request or add another SUM command without a BY phrase (and this would add another column to the report output).

**Example:** Sample Request Using a Parent/Child Hierarchy

A report request against a parent/child hierarchy can use the BY HIERARCHY phrase to report against the entire hierarchy. The output is automatically formatted with appropriate indentations to show the hierarchy levels and relationships.

For example, the following request shows the sales amount measure for three generations of the Organizations hierarchy:

```plaintext
TABLE FILE ADVENTURE_WORKS
SUM Amount
  BY AccountsCaption HIERARCHY
SHOW TO DOWN 3
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
END
```
The partial output is:

<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td>.00</td>
</tr>
<tr>
<td>Assets</td>
<td>13,740,731.00</td>
</tr>
<tr>
<td>Current Assets</td>
<td>12,445,628.00</td>
</tr>
<tr>
<td>Cash</td>
<td>3,236,799.00</td>
</tr>
<tr>
<td>Receivables</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Trade Receivables</td>
<td>3,371,580.00</td>
</tr>
<tr>
<td>Other Receivables</td>
<td>104,343.00</td>
</tr>
<tr>
<td>Allowance for Bad Debt</td>
<td>67,429.00</td>
</tr>
<tr>
<td>Inventory</td>
<td>4,143,398.00</td>
</tr>
<tr>
<td>Raw Materials</td>
<td>2,007,586.00</td>
</tr>
<tr>
<td>Work in Process</td>
<td>1,393,582.00</td>
</tr>
<tr>
<td>Finished Goods</td>
<td>742,230.00</td>
</tr>
<tr>
<td>Deferred Taxes</td>
<td>505,424.00</td>
</tr>
<tr>
<td>Prepaid Expenses</td>
<td>341,992.00</td>
</tr>
</tbody>
</table>

The report request does not have to reference specific hierarchy levels. The BY HIERARCHY phrase recreates and formats the hierarchy for display. You can also use a WHEN phrase to select a portion of the hierarchy and a SHOW phrase to specify how many levels above and below the selected portion of the hierarchy you want to display. This display format clearly shows the parent/child relationships between the hierarchy members.

For more information, see *Hierarchical Reporting* on page 2350.
Hierarchical Reporting

How to:
Display Parent/Child Hierarchies

Example:
Reporting on a Whole Hierarchy
Selecting a Hierarchy Member
Selecting a Member and Adding a Parent
Selecting a Member and Adding Children
Selecting a Member and Showing All Ascendants
Selecting a Member and Showing All Ascendants and Descendants
Using SKIP-LINE
Using Conditional Sort Options
Using Two BY HIERARCHY Phrases
Using BY HIERARCHY and BY Phrases
Using ON HIERARCHY Without BY HIERARCHY

When you issue a request against a cube, some of the requirements and features available depend on the type of hierarchy you are reporting against.

With a parent/child hierarchy, you can specify whether the measure values displayed for each parent should show the sum of all of its descendants (full total) or the sum of its displayed descendants (visual total).

Rollup using the MDX VISUALTOTALS function is a SSAS Adapter feature that enables you to select members using WHERE/IF clauses (for level hierarchies) or WHEN clauses (for parent/child hierarchies), and have the SSAS engine recalculate the values for the displayed members based on the report selection criteria. MDX is the language that is used by the SSAS engine.

For parent/child hierarchies, you can use the BY HIERARCHY phrase to sort and format the hierarchy. You can also limit the portion of the hierarchy selected for display using the WHEN phrase.

When a hierarchical request is processed, the first step is to build the hierarchy and mark which nodes should be included, which should be excluded, and which are needed for context.

The next stage fills the hierarchy with measure values.
Measure values cannot be used to select hierarchy levels for reporting. After the hierarchy rows have been selected, screened, and aggregated, WHERE TOTAL tests can limit the rows displayed based on measure values.

**Syntax:**

**How to Display Parent/Child Hierarchies**

The following syntax can be used to generate hierarchical reports when the synonym defines parent/child hierarchies:

```
SUM measure_field ...
BY hierarchy_field [HIERARCHY [WHEN expression_using_hierarchy_fields;]
[SHOW [TOP|UP n] [TO {BOTTOM|DOWN m} [byoption [WHEN condition] ...] ] ]
.
.
.
[ON hierarchy_field HIERARCHY [WHEN expression_using_hierarchy_fields;]
[SHOW [TOP|UP n] [TO BOTTOM|DOWN m] [byoption [WHEN condition] ...]]
```

where:

- `measure_field` is the field name of a measure.
- `hierarchy_field` identifies the hierarchy used for sorting.
- `hierarchy_field` identifies the hierarchy used for sorting. The request must include either a `BY` phrase or a `BY HIERARCHY` phrase for this field name.
- `WHEN expression_using_hierarchy_fields;` selects hierarchy members. The `WHEN` phrase must immediately follow the word `HIERARCHY` to distinguish it from a `WHEN` phrase associated with a `BY` option (such as `SUBFOOT`). Any expression using only hierarchy fields or properties is supported. The `WHEN` phrase can be on the `BY HIERARCHY` command or the `ON HIERARCHY` command, but not both.
- `SHOW` specifies which levels to show on the report output relative to the levels selected by the `WHEN` phrase. If there is no `WHEN` phrase, the `SHOW` option is applied to the root node of the hierarchy. The `SHOW` option can be specified on the `BY HIERARCHY` phrase or the `ON HIERARCHY` phrase, but not both.
\( n \)

Is the number of ascendants above the set of selected members that will have measure values. All ascendants appear on the report to show the hierarchical context of the selected members. However, ascendants that are not included in the SHOW phrase appear on the report with missing data symbols in the report columns that display measures. The default for \( n \) is 0.

**TOP**

Specifies that ascendant levels to the root node of the hierarchy will be populated with measure values.

**TO**

Is required when specifying a SHOW option for descendant levels.

**BOTTOM**

Specifies all descendants to the leaf nodes of the hierarchy will be populated with measure values. This is the default value.

\( m \)

Is the number of descendants of each selected level that will display. The default for \( m \) is BOTTOM, which displays all descendants.

**byoption**

Is one of the following sort-based options: PAGE-BREAK, REPAGE, RECAP, RECOMPUTE, SKIP-LINE, SUBFOOT, SUBHEAD, SUBTOTAL, SUB-TOTAL, SUMMARIZE, UNDER-LINE. If you specify SUBHEAD or SUBFOOT, you must place the WHEN phrase on the line following the heading or footing text.

**condition**

Is a logical expression.

**Note:** To generate a visual total (sum that represents only the displayed members) rather than a full total (value found in the cube), issue the SET ROLLUP_BY_VISUALTOTALS command.

The following examples illustrate hierarchical reporting using the BY HIERARCHY phrase. Note that requests with multiple display commands are not supported.

For information about using the MDX VISUALTOTALS function, see *Using the MDX VISUALTOTALS Function* on page 2329 and *Effect of MDX ROLLUP_BY_VISUALTOTALS Mode on Report Output* on page 2366.
**Example: Reporting on a Whole Hierarchy**

The following request displays the Amount measure for the Accounts hierarchy. The BY HIERARCHY phrase specifies hierarchical reporting. There is no WHEN phrase to limit the portion of the hierarchy displayed:

```
TABLE FILE ADVENTURE_WORKS
SUM Amount
BY Accounts_caption HIERARCHY
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Reporting on a Whole Hierarchy"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```
The top portion of the hierarchy is:

### Reporting on a Whole Hierarchy

<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td>.00</td>
</tr>
<tr>
<td>Assets</td>
<td>13,740,731.00</td>
</tr>
<tr>
<td>Current Assets</td>
<td>12,445,628.00</td>
</tr>
<tr>
<td>Cash</td>
<td>3,236,799.00</td>
</tr>
<tr>
<td>Receivables</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Trade Receivables</td>
<td>3,371,580.00</td>
</tr>
<tr>
<td>Other Receivables</td>
<td>104,243.00</td>
</tr>
<tr>
<td>Allowance for Bad Debt</td>
<td>67,429.00</td>
</tr>
<tr>
<td>Inventory</td>
<td>4,143,398.00</td>
</tr>
<tr>
<td>Raw Materials</td>
<td>2,007,586.00</td>
</tr>
<tr>
<td>Work in Process</td>
<td>1,393,582.00</td>
</tr>
<tr>
<td>Finished Goods</td>
<td>742,230.00</td>
</tr>
<tr>
<td>Deferred Taxes</td>
<td>505,424.00</td>
</tr>
<tr>
<td>Prepaid Expenses</td>
<td>341,992.00</td>
</tr>
<tr>
<td>Intercompany Receivables</td>
<td>674,663.00</td>
</tr>
<tr>
<td>Property, Plant, Equipment</td>
<td>1,122,394.00</td>
</tr>
<tr>
<td>Land &amp; Improvements</td>
<td>93,843.00</td>
</tr>
<tr>
<td>Buildings &amp; Improvements</td>
<td>299,043.00</td>
</tr>
<tr>
<td>Machinery &amp; Equipment</td>
<td>92,606.00</td>
</tr>
<tr>
<td>Office Furniture &amp; Equipment</td>
<td>523,016.00</td>
</tr>
<tr>
<td>Leasehold Improvements</td>
<td>80,759.00</td>
</tr>
<tr>
<td>Construction In Progress</td>
<td>33,127.00</td>
</tr>
<tr>
<td>Other Assets</td>
<td>172,709.00</td>
</tr>
<tr>
<td>Liabilities and Owners Equity</td>
<td>13,740,731.00</td>
</tr>
<tr>
<td>Liabilities</td>
<td>5,664,258.00</td>
</tr>
<tr>
<td>Current Liabilities</td>
<td>3,738,221.00</td>
</tr>
<tr>
<td>Notes Payable</td>
<td>148,316.00</td>
</tr>
<tr>
<td>Current Installments of Long-term Debt</td>
<td>149,571.00</td>
</tr>
<tr>
<td>Accounts Payable</td>
<td>1,286,664.00</td>
</tr>
<tr>
<td>Accrued Expenses</td>
<td>865,491.00</td>
</tr>
</tbody>
</table>
Example: Selecting a Hierarchy Member

The following request displays the Amount measure for the Accounts dimension, but limits the member selected for display with the WHEN phrase. Note that the hierarchy member selected is displayed in its context (all ancestors to the root of the hierarchy). However, the ancestors are not requested in the report and are, therefore, displayed with missing data symbols. All descendants of the selected members appear in the report output because the default SHOW option for descendants is BOTTOM:

```
TABLE FILE ADVENTURE_WORKS
SUM Amount
BY Accounts_caption HIERARCHY
WHEN Accounts_caption CONTAINS 'Receivables';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Hierarchy Member"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8, $
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

```
<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td></td>
</tr>
<tr>
<td>Assets</td>
<td></td>
</tr>
<tr>
<td>Current Assets</td>
<td></td>
</tr>
<tr>
<td>Receivables</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Trade Receivables</td>
<td>3,371,580.00</td>
</tr>
<tr>
<td>Other Receivables</td>
<td>104,343.00</td>
</tr>
<tr>
<td>Intercompany Receivables</td>
<td>674,663.00</td>
</tr>
</tbody>
</table>
```
**Example:** Selecting a Member and Adding a Parent

In the following request, the SHOW option UP 1 TO DOWN 0 added to the WHEN phrase adds the parent (Current Assets) of the selected member (Receivables). This parent now contains values for the measure rather than a missing data symbol:

```sql
TABLE FILE adventure_works
SUM Amount
BY Accounts_caption HIERARCHY
WHEN Accounts_caption EQ 'Receivables';
SHOW UP 1 TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding a Parent"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

```
<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td></td>
</tr>
<tr>
<td>Assets</td>
<td></td>
</tr>
<tr>
<td>Current Assets</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Receivables</td>
<td>3,475,923.00</td>
</tr>
</tbody>
</table>
```
**Example:** Selecting a Member and Adding Children

In the following request, the SHOW option UP 0 TO DOWN 1 added to the WHEN phrase adds the children of the selected member (Receivables):

```
TABLE FILE adventure_works
SUM Amount
BY Accounts_caption HIERARCHY
WHEN Accounts_caption EQ 'Receivables';
SHOW UP 0 TO DOWN 1
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding Children"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

```
<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td>.</td>
</tr>
<tr>
<td>Assets</td>
<td>.</td>
</tr>
<tr>
<td>Current Assets</td>
<td>.</td>
</tr>
<tr>
<td>Receivables</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Trade Receivables</td>
<td>3,371,580.00</td>
</tr>
<tr>
<td>Other Receivables</td>
<td>104,343.00</td>
</tr>
</tbody>
</table>
```
Example: Selecting a Member and Showing All Ascendants

In the following request, the SHOW option TOP TO DOWN 0 added to the WHEN phrase adds all ascendants but no descendants of the selected member (Receivables). These parents now contain values for the measure rather than missing data symbols:

```
TABLE FILE adventure_works
SUM Amount
BY Accounts_caption HIERARCHY
WHEN Accounts_caption EQ 'Receivables';
SHOW TOP TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding All Ascendants"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

```
Selecting a Member and Adding All Ascendants

<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td>.00</td>
</tr>
<tr>
<td>Assets</td>
<td>13,740,731.00</td>
</tr>
<tr>
<td>Current Assets</td>
<td>12,445,628.00</td>
</tr>
<tr>
<td>Receivables</td>
<td>3,475,923.00</td>
</tr>
</tbody>
</table>
```
**Example:** Selecting a Member and Showing All Ascendants and Descendants

In the following request, the SHOW option TOP added to the WHEN phrase adds all ascendants and descendants (since TO BOTTOM is the default) of the selected member (Receivables). These parents are now in the SHOW set and contain values for the measure rather than missing data symbols:

```sql
TABLE FILE adventure_works
SUM Amount
BY Accounts_caption HIERARCHY
WHEN Accounts_caption EQ 'Receivables';
SHOW TOP
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding All Ascendants and Descendants"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY= CENTER, $
END
```

The output is:

```
<table>
<thead>
<tr>
<th>Accounts Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td>-10,264,808.00</td>
</tr>
<tr>
<td>Assets</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Current Assets</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Receivables</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Trade Receivables</td>
<td>3,371,580.00</td>
</tr>
<tr>
<td>Other Receivables</td>
<td>104,343.00</td>
</tr>
</tbody>
</table>
```
Example: **Using SKIP-LINE**

The following request adds the BY option SKIP-LINE to the BY HIERARCHY phrase:

```sql
TABLE FILE adventure_works
SUM Amount
BY Accounts_caption HIERARCHY
WHEN Accounts_caption EQ 'Receivables';
SHOW UP 1 TO DOWN 1 SKIP-LINE
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using SKIP-LINE"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER,$
END
```

The output is:

```
Using SKIP-LINE

<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td></td>
</tr>
<tr>
<td>Assets</td>
<td></td>
</tr>
<tr>
<td>Current Assets</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Receivables</td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Trade Receivables</td>
<td>3,371,580.00</td>
</tr>
<tr>
<td>Other Receivables</td>
<td>104,343.00</td>
</tr>
</tbody>
</table>
```

Example: **Using Conditional Sort Options**

The following request has a BY HIERARCHY command with a WHEN phrase to select members as well as a WHEN phrase to control the UNDER-LINE option.

The SUBFOOT option is in an ON phrase that references the same hierarchy field (all of the BY options could have been on the BY HIERARCHY phrase).
Each BY option has its own WHEN phrase. The WHEN phrase for the SUBFOOT option uses a measure field in its expression. The WHEN phrase for the UNDER-LINE option uses a hierarchy field in its expression. The WHEN phrase that selects members uses a dimension property in its expression.

In this example, one BY option is activated WHEN the Accounts_caption contains Receivables. The other BY option creates a subfoot WHEN Amount is greater than or equal to $4,000,000:

```sql
TABLE FILE adventure_works
SUM Amount
BY Accounts_caption HIERARCHY
WHEN Account_Type EQ 'Assets';
SHOW TOP UNDER-LINE WHEN Accounts_caption CONTAINS 'Receivables';
ON Accounts_caption SUBFOOT
" "
"The Assets are Large"
" "
WHEN Amount GE 4000000;
ON TABLE SUBHEAD
"Using BY Options With WHEN on a Measure and a Hierarchy Field"
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```
The output is:

### Using BY Options With WHEN on a Measure and a Hierarchy Field

<table>
<thead>
<tr>
<th>Account</th>
<th>Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td>Asset</td>
<td>13,760,751.00</td>
</tr>
<tr>
<td>Current Assets</td>
<td></td>
<td>12,445,428.00</td>
</tr>
<tr>
<td>Cash</td>
<td></td>
<td>3,234,799.00</td>
</tr>
<tr>
<td>Receivables</td>
<td></td>
<td>3,475,923.00</td>
</tr>
<tr>
<td>Trade Receivables</td>
<td></td>
<td>3,371,380.00</td>
</tr>
<tr>
<td>Other Receivables</td>
<td></td>
<td>104,343.00</td>
</tr>
<tr>
<td>Allowance for Bad Debt</td>
<td></td>
<td>67,429.00</td>
</tr>
<tr>
<td>Inventory</td>
<td></td>
<td>4,143,398.00</td>
</tr>
<tr>
<td>Raw Materials</td>
<td></td>
<td>2,067,584.00</td>
</tr>
<tr>
<td>Work in Process</td>
<td></td>
<td>1,395,382.00</td>
</tr>
<tr>
<td>Finished Goods</td>
<td></td>
<td>742,230.00</td>
</tr>
<tr>
<td>Deferred Taxes</td>
<td></td>
<td>303,424.00</td>
</tr>
<tr>
<td>Prepaid Expenses</td>
<td></td>
<td>341,992.00</td>
</tr>
<tr>
<td>Intercompany Receivables</td>
<td></td>
<td>678,443.00</td>
</tr>
<tr>
<td>Property, Plant Equipment</td>
<td></td>
<td>1,122,394.00</td>
</tr>
<tr>
<td>Land &amp; Improvements</td>
<td></td>
<td>99,843.00</td>
</tr>
<tr>
<td>Building &amp; Improvements</td>
<td></td>
<td>299,043.00</td>
</tr>
<tr>
<td>Machinery &amp; Equipment</td>
<td></td>
<td>92,494.00</td>
</tr>
<tr>
<td>Office Furniture &amp; Equipment</td>
<td></td>
<td>323,014.00</td>
</tr>
<tr>
<td>Leasehold Improvement</td>
<td></td>
<td>60,759.00</td>
</tr>
<tr>
<td>Construction In Progress</td>
<td></td>
<td>33,127.00</td>
</tr>
<tr>
<td>Other Assets</td>
<td></td>
<td>172,769.00</td>
</tr>
</tbody>
</table>
**Example:** Using Two BY HIERARCHY Phrases

The following request has a BY HIERARCHY phrase for the Accounts hierarchy and a second BY HIERARCHY phrase for the Departments hierarchy (which is from a different dimension, as required). All selected members for the Accounts hierarchy are repeated for each selected member of the Departments hierarchy:

```
TABLE FILE adventure_works
SUM Amount
BY Accounts_caption HIERARCHY
WHEN Accounts_caption CONTAINS 'Receivables';
BY Departments_caption HIERARCHY
WHEN Departments_caption CONTAINS 'Sales';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using Two BY HIERARCHY Phrases"
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8, $
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

```
Using Two BY HIERARCHY Phrases

<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Departments Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Assets</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Current Assets</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Receivables</td>
<td>Corporate</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Sales and Marketing</td>
<td>3,475,923.00</td>
</tr>
<tr>

<tr>
<td></td>
<td>Sales and Marketing</td>
<td>674,663.00</td>
</tr>
</tbody>
</table>
```
**Example:** Using BY HIERARCHY and BY Phrases

The following request has a BY phrase for the Accounts hierarchy and a BY HIERARCHY phrase for the Departments hierarchy. All selected members for the Departments hierarchy are repeated for each selected member of the Accounts hierarchy (which is not displayed with hierarchical indentations when referenced in a BY phrase). A BY on a unique field is required. WHEN is used to select members for the BY HIERARCHY phrase. WHERE is used to select rows for the BY phrase:

```
TABLE FILE adventure_works
SUM Amount
BY Accounts_caption
BY Departments_caption HIERARCHY
WHEN Departments_caption OMITS 'Sales';
WHERE Accounts_caption CONTAINS 'Assets'
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using BY and BY HIERARCHY Phrases"
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```
Using **BY** and **BY HIERARCHY** Phrases

<table>
<thead>
<tr>
<th>Accounts</th>
<th>Member Caption</th>
<th>Departments</th>
<th>Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assets</td>
<td></td>
<td>Corporate</td>
<td>13,740,731.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Executive General and Administration</td>
<td>742,230.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Inventory Management</td>
<td>3,401,168.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Sales and Marketing</td>
<td>9,597,333.00</td>
<td></td>
</tr>
<tr>
<td>Current Assets</td>
<td></td>
<td>Corporate</td>
<td>12,445,628.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Executive General and Administration</td>
<td>742,230.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Inventory Management</td>
<td>3,401,168.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Sales and Marketing</td>
<td>8,302,230.00</td>
<td></td>
</tr>
<tr>
<td>Other Assets</td>
<td></td>
<td>Corporate</td>
<td>172,709.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Executive General and Administration</td>
<td>75,070.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Inventory Management</td>
<td>1,269.00</td>

</tr>
<tr>
<td></td>
<td></td>
<td>Manufacturing</td>
<td>2,583.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Quality Assurance</td>
<td>1,728.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Research and Development</td>
<td>26,752.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Sales and Marketing</td>
<td>172,709.00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Sales and Marketing</td>
<td>1,901.00</td>
<td></td>
</tr>
</tbody>
</table>

**Example:** Using **ON HIERARCHY Without BY HIERARCHY**

The following request has a **BY** phrase and an **ON HIERARCHY** phrase for the Departments hierarchy. All hierarchy options and **BY** options are supported on the **ON HIERARCHY** phrase. This request also has a **WHEN** clause that selects members based on the value of a hierarchy field (Departments_caption):

```
TABLE FILE adventure_works
SUM Amount
BY Departments_caption
ON Departments_caption HIERARCHY
WHEN Departments_caption OMITS 'Sales';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using ON HIERARCHY"
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8, $;
TYPE=REPORT, GRID=OFF, WRAP=OFF, $;
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $;
END
```
The output is:

Using ON HIERARCHY

<table>
<thead>
<tr>
<th>Department Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Corporate</td>
<td>12,609,503.00</td>
</tr>
<tr>
<td>Executive General and Admin</td>
<td>-396,702.00</td>
</tr>
<tr>
<td>Inventory Management</td>
<td>-1,315,294.00</td>
</tr>
<tr>
<td>Manufacturing</td>
<td>-826,648.00</td>
</tr>
<tr>
<td>Quality Assurance</td>
<td>-574,566.00</td>
</tr>
<tr>
<td>Research and Development</td>
<td>28,625,144.00</td>
</tr>
<tr>
<td>Sales and Marketing</td>
<td>-639,841.00</td>
</tr>
</tbody>
</table>

Effect of MDX ROLLUP_BY_VISUALTOTALS Mode on Report Output

In this section:
- Reporting Against Level Hierarchies
- Hierarchical Reporting From Parent-Child Hierarchies
- Reporting Without Sort/Grouping

When reporting against SQL Server Analysis Services (SSAS) cubes, by default, the report output displays the visual totals, not the measure values stored in the cube cells for members that are displayed on the report output. The values displayed are determined by the report selection criteria and dimension levels referenced in the sort phrases (BY and ACROSS) for level hierarchies, or explicit member selection for Parent/Child hierarchies and dimensions not referenced by sort phrases.

To retrieve data from a SSAS cube, the adapter translates the WebFOCUS request to MDX, the language that is used by the SSAS engine. By default, the adapter uses the MDX VISUALTOTALS function. SSAS then returns the requested cells with visual totals.

You can set ROLLUP_BY_VISUALTOTALS OFF if you want values that are aggregates resulting from rolling up measures along the cube dimensions when the cube was processed, and are based on rolling up all the underlying members of the hierarchy even if the report performs some selection on the levels below the displayed ones.

Rollup using the MDX VISUALTOTALS function is a SSAS Adapter feature that enables you to select members using WHERE/IF clauses (for level hierarchies) or WHEN clauses (for parent/child hierarchies), and have the SSAS engine recalculate the values for the displayed members based on the report selection criteria.

To see complete syntax for the SET ROLLUP_BY_VISUALTOTALS command, see Using the MDX VISUALTOTALS Function on page 2329.
Reporting Against Level Hierarchies

Example:
Level Hierarchies With Sort/Grouping
Level Hierarchies With Calculated Measures

Level hierarchies are presented in WebFOCUS synonyms as sets of fields consisting of one mandatory field per hierarchy level (for member captions) and a field per a user-defined property (attribute relationship) associated with the given level. The adapter employs the VISUALTOTALS function when the hierarchy levels referenced in filter conditions (WHERE, IF clauses) are below the levels selected for sort/grouping (BY clauses). The set of members to which the VISUALTOTALS function is applied consists of all the filtered members and their hierarchical ascendants up to (but not above) the lowest level selected for sort/grouping.

Example:  Level Hierarchies With Sort/Grouping
Consider the following hierarchy flattened into a table:

<table>
<thead>
<tr>
<th>Country</th>
<th>State/Province</th>
<th>City</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>New South Wales</td>
<td>Coffs Harbour</td>
</tr>
<tr>
<td>Australia</td>
<td>New South Wales</td>
<td>Darlinghurst</td>
</tr>
<tr>
<td>Australia</td>
<td>New South Wales</td>
<td>Goulburn</td>
</tr>
<tr>
<td>Australia</td>
<td>Victoria</td>
<td>Melbourne</td>
</tr>
<tr>
<td>Australia</td>
<td>Victoria</td>
<td>Sunbury</td>
</tr>
<tr>
<td>Canada</td>
<td>British Columbia</td>
<td>Burnaby</td>
</tr>
<tr>
<td>Canada</td>
<td>British Columbia</td>
<td>Cliffside</td>
</tr>
<tr>
<td>United States</td>
<td>California</td>
<td>Los Angeles</td>
</tr>
<tr>
<td>United States</td>
<td>California</td>
<td>San Francisco</td>
</tr>
<tr>
<td>United States</td>
<td>Oregon</td>
<td>Lebanon</td>
</tr>
<tr>
<td>United States</td>
<td>Oregon</td>
<td>Portland</td>
</tr>
<tr>
<td>United States</td>
<td>Washington</td>
<td>Bellevue</td>
</tr>
</tbody>
</table>
### Table 1: Selected Hierarchical Paths

<table>
<thead>
<tr>
<th>Country</th>
<th>State/Province</th>
<th>City</th>
</tr>
</thead>
<tbody>
<tr>
<td>United States</td>
<td>Washington</td>
<td>Seattle</td>
</tr>
<tr>
<td>United States</td>
<td>Washington</td>
<td>Spokane</td>
</tr>
</tbody>
</table>

Each row in the table corresponds to a hierarchical path. The following WebFOCUS query selects some paths from the hierarchy using a WHERE clause:

```sql
TABLE FILE ADVENTURE_WORKS
WRITE INTERNET_SALES_AMOUNT
BY COUNTRY
WHERE CITY EQ 'Coffs Harbour' OR 'Darlinghurst' OR 'Melbourne'
    OR 'Portland' OR 'Seattle' OR 'Spokane';
END
```

The following hierarchical paths are selected:

<table>
<thead>
<tr>
<th>Country</th>
<th>State/Province</th>
<th>City</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>New South Wales</td>
<td>Coffs Harbour</td>
</tr>
<tr>
<td>Australia</td>
<td>New South Wales</td>
<td>Darlinghurst</td>
</tr>
<tr>
<td>Australia</td>
<td>Victoria</td>
<td>Melbourne</td>
</tr>
<tr>
<td>United States</td>
<td>Oregon</td>
<td>Portland</td>
</tr>
<tr>
<td>United States</td>
<td>Washington</td>
<td>Seattle</td>
</tr>
<tr>
<td>United States</td>
<td>Washington</td>
<td>Spokane</td>
</tr>
</tbody>
</table>

The BY COUNTRY phrase determines that members for reporting are selected on the level of Country. The following MDX query is a simplified version of the actual MDX generated by the adapter when ROLLUP_BY_VISUALTOTALS is set to OFF:

```mdx
Select {[Internet Sales Amount]} on Axis(0),
    {[Australia], [United States]} on Axis(1) From [Adventure Works]
```
The report has the following contents, where the values of the measure Internet Sales Amount are extracted for members Australia and United States as they are rolled up in the cube, not just for the cities selected by the WHERE criteria. This is the default adapter behavior:

<table>
<thead>
<tr>
<th>Country</th>
<th>Internet Sales Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>$9,061,000.58</td>
</tr>
<tr>
<td>United States</td>
<td>$9,389,789.51</td>
</tr>
</tbody>
</table>

For some applications, it is desirable that the values of Country level members shown in the report are not the values that are stored in the cube but rather values rolled up based only on the selected members of City level. In this case, the Internet Sales Amount value of Australia would be the sum of Internet Sales Amount for Coffs Harbour, Darlinghurst, and Melbourne, and the value for United States would be the sum of values for Portland, Seattle, and Spokane.

To do this, the adapter generates an MDX query using the MDX VISUALTOTALS function.

Note that the six selected hierarchical paths form two subtrees. Applying the VISUALTOTALS function to the set of members that form these subtrees and then intersecting the result with the members of the Country level provides the values for Australia and United States rolled up based on the selected cities only. The WebFOCUS request is:

```
TABLE FILE ADVENTURE_WORKS
WRITE INTERNET_SALES_AMOUNT
BY COUNTRY
WHERE CITY EQ 'Coffs Harbour' OR 'Darlinghurst' OR 'Melbourne'
OR 'Portland' OR 'Seattle' OR 'Spokane';
END
```

The following is a simplified version of the MDX query generated by the adapter to achieve the visual total.

```
Select {[Internet Sales Amount]} on Axis(0),
Intersect(
VisualTotals({[Australia], [New South Wales], [Coffs Harbour],
[Darlinghurst],
[Victoria], [Melbourne],
[United States],[Oregon],[Portland],
[Washington],[Seattle],[Spokane]})
), [Customer Geography].[Country].Members) on Axis(1)
From [Adventure Works]
```
The values that result from this query are not the values for Australia and United States taken from the cube but rather values rolled up by SSAS from the selected cities:

<table>
<thead>
<tr>
<th></th>
<th>Internet Sales Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>$637,022.87</td>
</tr>
<tr>
<td>United States</td>
<td>$254,920.12</td>
</tr>
</tbody>
</table>

**Example: Level Hierarchies With Calculated Measures**

The following example shows how visual totals work for calculated measures. The calculated measure [Internet Average Unit Price] is defined by the following expression:

\[
\text{[Internet Unit Price]} / \text{[Internet Transaction Count]}
\]

where [Internet Unit Price] and [Internet Transaction Count] are measures that are not visible in the Adventure Works cube metadata (and, therefore, the WebFOCUS synonym does not contain corresponding fields for them). Using the MDX VISUALTOTALS function, the following WebFOCUS query returns correct results for the selected countries based only on the selected cities:

```
TABLE FILE ADVENTURE_WORKS
WRITE INTERNET_AVERAGE_UNIT_PRICE/F12.2
BY COUNTRY
WHERE CITY EQ 'Coffs Harbour' OR 'Darlinghurst' OR 'Melbourne'
OR 'Portland' OR 'Seattle' OR 'Spokane';
END
```

The output is:

<table>
<thead>
<tr>
<th></th>
<th>Internet Average Unit Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Australia</td>
<td>597.02</td>
</tr>
<tr>
<td>United States</td>
<td>354.06</td>
</tr>
</tbody>
</table>
Hierarchical Reporting From Parent-Child Hierarchies

Example:
Retrieving Visual Totals in a Hierarchical Report

Reference:
Reporting From Parent-Child Hierarchies With BY and WHERE Clauses

In hierarchical reports, the selected members (specified by WHEN and SHOW clauses) are always shown in their hierarchical context so that the report forms a contiguous subtree (or, if and only if the hierarchy has multiple roots, several subtrees). The values of the requested members are, by default, rolled up, not just extracted from the cube.

The exact set to which the VISUALTOTALS function is applied consists of the members selected by WHEN and SHOW clauses plus connecting members in the hierarchy. WHEN and SHOW clauses may select one or more pairs of members, one of which is an ancestor of another (and the second of which is a descendant of the first) but not the members in between. The adapter calls the VISUALTOTALS function to add all intermediate members connecting these two members to the set to which the VISUALTOTALS function is applied. This is done to ensure its proper functioning. Members below or above this connected set are not added.

Reference: Reporting From Parent-Child Hierarchies With BY and WHERE Clauses

Parent-Child hierarchies can be used for regular reporting with BY and WHERE clauses as opposed to BY HIERARCHY and WHEN. In that case, all members of a hierarchy are viewed as a flat stream without any hierarchical relationship. A report shows the selected members in a single column sorted according to the specified BY clause. In this case the notion of visual totals is not applicable.

Example: Retrieving Visual Totals in a Hierarchical Report

Consider the following WebFOCUS hierarchical reporting query:

```sql
ENGINE SSAS SET ROLLUP_BY_VISUALTOTALS OFF
TABLE FILE ADVENTURE_WORKS
WRITE AMOUNT
BY ACCOUNTS.Caption
HIERARCHY
WHEN ACCOUNTS.Caption EQ 'Balance Sheet'
OR 'Assets' OR 'Liabilities and Owners Equity'
OR 'Cash'
OR 'Current Liabilities' OR 'Long Term Liabilities';
SHOW UP 0 TO DOWN 0
END
```
This results in the following report:

<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td>0.00</td>
</tr>
<tr>
<td>Assets</td>
<td>13,740,731.00</td>
</tr>
<tr>
<td>Current Assets</td>
<td>.</td>
</tr>
<tr>
<td>Cash</td>
<td>3,236,799.00</td>
</tr>
<tr>
<td>Liabilities and Owners Equity</td>
<td>13,740,731.00</td>
</tr>
<tr>
<td>Liabilities</td>
<td>.</td>
</tr>
<tr>
<td>Current Liabilities</td>
<td>3,738,221.00</td>
</tr>
<tr>
<td>Long Term Liabilities</td>
<td>1,926,037.00</td>
</tr>
</tbody>
</table>

To show values of these members not as they are in the cube but rolled up only from its descendants shown in the same report, remove the SET VISUALTOTALS OFF command:

```
TABLE FILE ADVENTURE_WORKS
WRITE AMOUNT/D12.2BM
BY ACCOUNTS_CAPTION
HIERARCHY
WHEN ACCOUNTS_CAPTION EQ 'Balance Sheet'
OR 'Assets' OR 'Liabilities and Owners Equity'
OR 'Cash'
OR 'Current Liabilities' OR 'Long Term Liabilities';
SHOW UP 0 TO DOWN 0
END
```
The exact set to which the VISUALTOTALS function is applied consists of the members selected by WHEN and SHOW clauses plus connecting members. WHEN and SHOW clauses may select one or more pairs of members one of which is an ancestor of another but not the members in between (Assets and Cash in the following output). The adapter adds all intermediate members connecting these two members to the set to which the VISUALTOTALS function is applied. This is done to ensure its proper functioning. Members below or above this connected set are not added:

### Reporting Without Sort/Grouping

<table>
<thead>
<tr>
<th>Accounts Member Caption</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balance Sheet</td>
<td>($2,427,459.00)</td>
</tr>
<tr>
<td>Assets</td>
<td>$3,236,799.00</td>
</tr>
<tr>
<td>Current Assets</td>
<td></td>
</tr>
<tr>
<td>Cash</td>
<td>$3,236,799.00</td>
</tr>
<tr>
<td>Liabilities and Owners Equity</td>
<td>$5,664,258.00</td>
</tr>
<tr>
<td>Liabilities</td>
<td></td>
</tr>
<tr>
<td>Current Liabilities</td>
<td>$3,738,221.00</td>
</tr>
<tr>
<td>Long Term Liabilities</td>
<td>$1,926,037.00</td>
</tr>
</tbody>
</table>

**Example:**

Reporting Against Hierarchies Without Sort/Grouping

The VISUALTOTALS function is applied to the set consisting of all ascendants of the selected members and then extracting their lowest common ancestor.

If selected members do not have common ancestors, the adapter creates one by applying function AGGREGATE to the ancestors of the selected members on the topmost level of the hierarchy. This aggregate value is then displayed on the report output.
**Example:** Reporting Against Hierarchies Without Sort/Grouping

Consider the following WebFOCUS query:

```sql
TABLE FILE ADVENTURE_WORKS
WRITE INTERNET_SALES_AMOUNT
WHERE COUNTRY EQ 'Canada' OR STATE_PROVINCE EQ 'Washington';
END
```

The default behaviour results in the combined value of both Canada and Washington members.

Since the selected members do not have common ancestors, with visual totals on, the adapter creates one by applying function AGGREGATE to the ancestors of the selected members on the topmost level of the hierarchy. This aggregate value is then displayed on the report output:

```
| Internet Sales Amount | $4,445,093.20 |
```

In this example, the generated MDX is equivalent to the following:

```mdx
Select {[Internet Sales Amount]} on Axis(0),
Intersect(
VisualTotals({[Customer].[Customer Geography].[All],
[Canada],
[United States],
[Washington]},
[Customer Geography].[All].Members)
on Axis(1)
From [Adventure Works]
```

Adding the SET ROLLUP_BY_VISUALTOTALS OFF command results in the following report in which the values are shown separately for Canada and Washington:

```
<table>
<thead>
<tr>
<th>Internet Sales Amount</th>
<th>$1,977,844.86</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>$2,467,248.34</td>
</tr>
</tbody>
</table>
```
Reporting on SQL Server Analysis Services (SSAS) Sets

**How to:**
Select or Exclude Set Members

**Example:**
Finding the Name of a Set
Selecting Members of a Set

A named set is a group of members from one or more hierarchies. WebFOCUS supports named sets in which the members all come from a single hierarchy. When you create a synonym, for each hierarchy that has one or more single-hierarchy named sets, a field with a _SETS suffix is generated. The value stored in this field is the name of one or more sets defined for the associated hierarchy. A SETS field has the attribute PROPERTY=SETS.

You can find the name of a set by printing the value of its associated field. When a SETS field is used in a PRINT command, it must be the only active field in the TABLE request. Once you know the name of a set, you can use it in:

- A WHERE or IF phrase when reporting on a level hierarchy.
- A WHEN phrase when reporting on a parent/child hierarchy.

An expression referencing a named set can only consist on EQ and NE conditions. The EQ condition selects all members of the set, and the NE condition excludes all members in the set.

**Note:** In order to issue a request that performs a selection on a SET, the ROLLUP_BY_VISUALTOTALS parameter must be set to OFF.

Set members can come from different levels in a hierarchy. If a WHERE or SHOW condition limits the portion of the hierarchy being displayed on the report output, only the set members applicable to those hierarchy levels are shown.

**Syntax:**  **How to Select or Exclude Set Members**

For columnar reporting use the following type of expression in one or more WHERE or IF clauses. For hierarchical reporting, use the following type of expression in a WHEN clause:

```plaintext
{WHERE WHEN} field1_SETS {EQ|NE} setname11 [OR setname12 ...]
[{AND|OR} field2_SETS {EQ|NE} setname21 [OR setname22]... ]

IF field1_SETS {EQ|NE} setname11 [OR setname12 ...]
IF field2_SETS {EQ|NE} setname21 [OR setname22 ...]
```

Adapter Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS 2375
where:

field1_SETS

Is a field name with the _SETS extension that contains the names of one or more sets defined for a hierarchy.

setname11, setname12, setname21, setname22

Are the names of sets. The set names setname11 and setname12 are stored in field1_SETS. The set names setname21 and setname22 are stored in field2_SETS.

EQ

Selects members of the associated set.

NE

Excludes members of the associated set.

Example: Finding the Name of a Set

The following request finds the sets defined for the Products hierarchy by printing the value of its SETS field (Product_Product_Categories_SETS):

```
TABLE FILE adventure_works
PRINT Product_Product_Categories_SETS
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Finding the Name of a SET"
ON TABLE SET STYLE *
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output shows that the only set defined for this hierarchy is named Core Product Group:
Example: Selecting Members of a Set

The following request selects the members of the Core Product Group set from the Products hierarchy. It further limits the output with a WHERE clause on the Category1 field. ROLLUP_BY_VISUALTOTALS is not supported with this type of query:

```
ENGINE SSAS SET ROLLUP_BY_VISUALTOTALS OFF
TABLE FILE adventure_works
SUM Internet_Sales_Amount
BY Category1
BY Subcategory1
BY Product
WHERE Product_Product_Categories_SETS EQ 'Core Product Group'
WHERE Category1 EQ 'Clothing'
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Reporting on a Set"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```
Reporting on Key Performance Indicators

Example:
Sample Growth in Customer Base KPI for the Adventure Works Cube
Sample Request Using the Growth in Customer Base KPI

Reference:
KPI Metadata in a Synonym

If a Microsoft SQL Server Analysis data source has Key Performance Indicators (KPIs) defined, you can access and display these performance measures in a WebFOCUS report.

<table>
<thead>
<tr>
<th>Category</th>
<th>Subcategory</th>
<th>Product</th>
<th>Internet Sales Amount</th>

</tbody>
</table>
A KPI is a calculation or set of calculations against measures in the cube that typically represent a value, status, trend, or goal. It is stored with properties that enable the organization to set and track progress toward a specified level for the KPI goal. The KPI Value represents the current state of the indicator, and the KPI Goal represents the state toward which the organization is aiming. The KPI Status and KPI Trend are derived by comparing the Goal with the Value.

If the cube has KPIs defined, any synonym created will automatically contain metadata for those KPIs.

**Reference: KPI Metadata in a Synonym**

The metadata for a KPI starts with the following KPI declaration in the Master File:

```
KPI=kpiname,
    CAPTION=kpi_caption,
    KPI_STATUS_ICON='kpi_status_graphic',
    KPI_TREND_ICON='kpi_trend_graphic'
   [,PARENT=kpi_parent_kpiname] ,$
```

where:

- `kpiname` is the name of the KPI.
- `kpi_caption` is the caption for the KPI.
- `kpi_status_graphic` is the graphic assigned to the KPI Status property.
- `kpi_trend_graphic` is the graphic assigned to the KPI Trend property.
- `kpi_parent_kpiname` if the KPI is part of a hierarchy of KPIs, this is the name of the parent KPI.

Field declarations describing the KPI properties follow the KPI declaration. Only the VALUE field is required, the GOAL, STATUS, and TREND fields are optional.

The following field declaration describes the KPI Value property and is required:

```
FIELDNAME=kpiname_KPI_VALUE,
    ALIAS=('[Measures].[kpiname]', USAGE=Ann, ACTUAL=Ann, MISSING=ON,
    TITLE='kpi_value_title',
    REFERENCE='kpiname',
    PROPERTY=KPI_VALUE, $
```
where:

\textit{kpiname\_KPI\_VALUE}

Is the field name for the KPI Value property.

\textit{kpiname}

Is the name of the KPI.

\textit{kpi\_value\_title}

Is the column title for the KPI Value field.

The following field declarations represent the KPI Goal, Status, and Trend properties. One or more of them may be present, but they are not required:

\begin{verbatim}
FIELDNAME=kpiname\_KPI\_GOAL,
   ALIAS='[Measures].[kpiname]', USAGE=Ann, ACTUAL=Ann, MISSING=ON,
   TITLE='kpi\_goal\_title',
   REFERENCE='kpiname',
   PROPERTY=KPI\_GOAL, $

FIELDNAME=kpiname\_KPI\_STATUS,
   ALIAS='[Measures].[kpiname]', USAGE=Dn.m, ACTUAL=D8, MISSING=ON,
   TITLE='kpiname\_status\_title',
   REFERENCE='kpiname',
   PROPERTY=KPI\_STATUS, $

FIELDNAME=kpiname\_KPI\_TREND,
   ALIAS='[Measures].[kpiname]', USAGE=Dn.m, ACTUAL=D8, MISSING=ON,
   TITLE='kpiname\_trend\_title',
   REFERENCE='kpiname',
   PROPERTY=KPI\_TREND, $
\end{verbatim}

where:

\textit{kpiname\_KPI\_GOAL, kpiname\_KPI\_STATUS, kpiname\_KPI\_TREND}

Are the field names for the KPI Value, Status, and Trend properties.

\textit{kpiname}

Is the name of the KPI.

\textit{kpi\_goal\_title, kpi\_status\_title, kpi\_trend\_title}

Are the column titles for the KPI Goal, Status, and Trend fields.
Example: **Sample Growth in Customer Base KPI for the Adventure Works Cube**

The following declarations define the *Growth in Customer Base* KPI for the Adventure Works cube:

```plaintext
KPI=Growth in Customer Base,
    CAPTION='Growth in Customer Base',
    KPI_STATUS_ICON='Road Signs',
    KPI_TREND_ICON='Standard Arrow',
FIELDNAME=Growth_in_Customer_Base_KPI_VALUE,
    ALIAS='[Measures].[Growth in Customer Base]', USAGE=A20, ACTUAL=A20,
    MISSING=ON,
    TITLE='Growth in Customer Base Value',
    REFERENCE='Growth in Customer Base',
    PROPERTY=KPI_VALUE,
FIELDNAME=Growth_in_Customer_Base_KPI_GOAL,
    ALIAS='[Measures].[Growth in Customer Base Goal]', USAGE=A20, ACTUAL=A20,
    MISSING=ON,
    TITLE='Growth in Customer Base Goal',
    REFERENCE='Growth in Customer Base',
    PROPERTY=KPI_GOAL,
FIELDNAME=Growth_in_Customer_Base_KPI_STATUS,
    ALIAS='[Measures].[Growth in Customer Base Status]', USAGE=D5.2,
    ACTUAL=D8, MISSING=ON,
    TITLE='Growth in Customer Base Status',
    REFERENCE='Growth in Customer Base',
    PROPERTY=KPI_STATUS,
FIELDNAME=Growth_in_Customer_Base_KPI_TREND,
    ALIAS='[Measures].[Growth in Customer Base Trend]', USAGE=D5.2,
    ACTUAL=D8, MISSING=ON,
    TITLE='Growth in Customer Base Trend',
    REFERENCE='Growth in Customer Base',
    PROPERTY=KPI_TREND,
```

Example: **Sample Request Using the Growth in Customer Base KPI**

The following request displays the *Growth in Customer Base* KPI value by fiscal year:

```plaintext
TABLE FILE ADVENTURE_WORKS
WRITE GROWTH_IN_CUSTOMER_BASE_KPI_VALUE/A6
BY FISCAL_YEAR
END
```

The output is:

```
Fiscal Year  Growth in Customer Base Value
------------- -----------------------------
FY 2003     0.4605
FY 2004     4.4040
FY 2005     -0.946
```
Using the Adapter for Sybase

The Adapter for Sybase allows applications to access Sybase data sources. Both Sybase ASE and Sybase IQ servers are supported.

The adapter converts application requests into native Sybase statements and returns optimized answer sets to the requesting application.

Topics:
- Preparing the Sybase Environment
- Configuring the Adapter for Sybase
- Managing Sybase Metadata
- Reporting Against a Sybase Stored Procedure
- Customizing the Sybase Environment
- Optimization Settings
- Calling a Sybase Stored Procedure Using SQL Passthru
Preparing the Sybase Environment

In this section:
- Identifying the Location of the Interfaces File
- Specifying the Sybase Server Name
- Accessing a Remote Sybase Server
- Unicode Support
- XA Support (ASE)

The Adapter for Sybase requires the installation of the Sybase Open Client (CT-Library). The Sybase client allows you to connect to a local or remote Sybase database server after the platform-specific environment variables are set. After installation, the client must be configured to allow you to connect to a local or remote Sybase database server.

Identifying the Location of the Interfaces File

If you are using Sybase inherent distributed access, you must set the SYBASE environment variable to identify the directory where the interfaces file resides. The Windows equivalent of the UNIX interfaces file is the sql.ini file.

The interfaces file is required for both local and remote access. If you do not set the SYBASE environment variable, Sybase searches /etc/passwd for the login directory of the user named Sybase and accesses the interfaces file in that directory.

Note that the UNIX PATH must include the location of the Sybase executables. For example, specify the PATH entry as follows for Sybase:

```
SYBASE=/usr/sybase
PATH=$PATH:$SYBASE/bin
export SYBASE PATH
```

You can export the SYBASE environment variable from the UNIX shell or in the UNIX profile of the user’s machine that starts the server.

For information about other environment variables needed for Sybase executables and components, see the Sybase installation and configuration documentation.
Specifying the Sybase Server Name

**How to:**

Specify the Sybase Server Name

Use the DSQUERY environment variable to specify the Sybase Server name. The server uses this value only if:

- You do not issue the SET CONNECTION_ATTRIBUTES command in the global server profile (edasprof.prf).
- You do not specify the CONNECTION= attribute in the Access File.

**Procedure: How to Specify the Sybase Server Name**

```bash
DSQUERY=server
export DSQUERY
```

where:

```
server
```

Is the name of the Sybase database server.

Accessing a Remote Sybase Server

Using the standard rules for deploying the Sybase Client, the server supports connections to:

- Local Sybase servers.
- Remote Sybase servers. To connect to a remote Sybase server, the `interfaces` file (`sql.ini` on Windows) must contain an entry pointing to the target machine and the listening process must be running on the target machine.

New entries in the `interfaces` file may be made using the Sybase tool DSEDIT. Entries may also be made automatically using the sybinstall facility. For details, see the Sybase documentation.

Unicode Support

**For ASE,** beginning with Sybase ASE version 15.0, the adapter supports Unicode data in Sybase ASE databases that have been created with the UTF-8 character set.

**For IQ,** beginning with Sybase IQ version 12.7, the adapter supports Unicode data in Sybase IQ databases that have been created with the UTF-8 character set.
You must set the LANG and NLS_LANG environment variables in the edastart file or in a separate shell file before starting the server.

For example, for American English, you would export the following variables:

```bash
export LANG=EN_US.UTF-8
export NLS_LANG=American_America.UTF8
```

**Note:** To take advantage of the adapter support for Unicode data, the Reporting Server must be configured with UTF-8 code page 65001.

**XA Support (ASE)**

Read/write applications accessing Sybase data sources are able to perform transactions managed in XA-compliant mode.

To activate the XA Transaction Management feature, the server has to be configured in Transaction Coordination Mode, using the Web console configuration functions. Using Transaction Coordination Mode guarantees the integrity of data modification on all of the involved DBMSs and protects part of the data modifications from being committed on one DBMS and terminated on another.

For complete documentation on XA compliance, see [XA Support](#) on page 2757.

**Configuring the Adapter for Sybase**

<table>
<thead>
<tr>
<th>In this section:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Declaring Connection Attributes</td>
</tr>
<tr>
<td>Overriding the Default Connection</td>
</tr>
<tr>
<td>Controlling the Connection Scope</td>
</tr>
</tbody>
</table>

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Declaring Connection Attributes

How to:
- Declare Connection Attributes
- Declare Connection Attributes Manually

Example:
- Declaring Connection Attributes

Reference:
- Connection Attributes for Sybase

In order to connect to the Sybase database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one Sybase database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the Sybase Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters or from the Data Management Console, expand the Adapters folder.
Configuring the Adapter for Sybase

The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right click the adapter name/version and select Configure.

The Add Adapter to Configuration pane opens.

If you are using a Sybase ASE database, click either OCS 15 to connect to the OCS client, which in turn connects to the 15 version of Sybase ASE, or click Sybase ASE 12.5 to connect to the older version of the database.

If you are using a Sybase IQ database, click either OCS 15 to connect to the OCS client, which in turn connects to the 15 version of Sybase IQ, or click Sybase IQ 12.5 to connect to the older version of the database.

5. Enter values for the parameters required by the adapter as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for Sybase

The Sybase adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Server

Name of the Sybase server to access. It must match an entry in the Sybase interfaces file.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.
**Password**

Password associated with the primary authorization ID.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:**

**How to Declare Connection Attributes Manually**

**Explicit authentication.** The user ID and password are explicitly specified for each connection and passed to Sybase, at connection time, for authentication.

ENGINE SQLSYB SET CONNECTION_ATTRIBUTES server/userid,password

**Password passthru authentication.** The user ID and password are explicitly specified for each connection and passed to Sybase, at connection time, for authentication.

ENGINE SQLSYB SET CONNECTION_ATTRIBUTES server/

where:

- **SQLSYB**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **server**
  Is the name of the Sybase server you wish to access.

- **userid**
  Is the primary authorization ID by which you are known to Sybase.

- **password**
  Is the password associated with the primary authorization ID.
Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to the Sybase database server named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE SQLSYB SET CONNECTION_ATTRIBUTES SAMPLESERVER/MYUSER,PASS
```

The following SET CONNECTION_ATTRIBUTES command connects to the Sybase database server named SAMPLESERVER using Password Passthru authentication:

```
ENGINE SQLSYB SET CONNECTION_ATTRIBUTES SAMPLESERVER/
```

Overriding the Default Connection

How to:

Change the Default Connection

Example:

Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE SQLSYB SET DEFAULT_CONNECTION connection
```

where:

- **SQLSYB**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```
Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  FOC1671, Command out of sequence.

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

ENGINE SQLSYB SET DEFAULT_CONNECTION SAMPLENAME

Controlling the Connection Scope

How to:
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

ENGINE SQLSYB SET AUTODISCONNECT ON {FIN | COMMAND | COMMIT}

where:

SQLSYB
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN
Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMAND
Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.
COMMIT
Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Sybase Metadata

In this section:
Creating Synonyms
Accessing Different Databases on the Same Sybase Server
Sybase Data Type Support
Controlling the Mapping of Large Character Data Types
Controlling the Mapping of Variable-Length Data Types
Trailing Blanks in SQL Expressions
Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Sybase data types.
Creating Synonyms

How to:
Create a Synonym

Example:
Sample Generated Synonym

Reference:
Synonym Creation Parameters for Sybase
Mapping Sybase IQ Table Comments Into a Synonym
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each Sybase table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source's location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server’s metadata.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
The Status pane indicates that the synonym was created successfully. The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.
- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:** Synonym Creation Parameters for Sybase

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters ("," or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Database selection**

To specify a database from which you can select a table or other object, do one of the following:

- Check *Use current database* to use the database that has been set as the default database.
- Select a database from the *Select database* drop-down list, which lists all databases in the current DBMS instance.

Before selecting a database, if *Use current database* is checked, uncheck it.

This option applies to Sybase ASE; it does not apply to Sybase IQ.
Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the **Base Location** field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the **Document Name** field, enter the file name with or without wild card characters.

- In the **Document Extension** field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the **Base Location** field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The **Document Extension** is understood to be MBR. You can enter this value explicitly or leave the input box blank.
During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the **Cardinality** check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

**With foreign key**

Select the **With foreign key** check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the **Dynamic columns** check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when **External SQL Scripts** is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.
Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Sybase Data Type Support on page 2402.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Sybase synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.
Generated Master File

FILENAME=N29004, SUFFIX=SQLSYB, $ 
SEGMENT=N29004, SEGTYPE=S0, $ 
FIELDNAME=DIVISION4, ALIAS=DIVISION4, USAGE=I11, ACTUAL=I4, $ 
FIELDNAME=DIVISION_NA4, ALIAS=DIVISION_NA4, USAGE=A25, ACTUAL=A25, 
MISSING=ON, $ 
FIELDNAME=DIVISION_HE4, ALIAS=DIVISION_HE4, USAGE=I11, ACTUAL=I4, 
MISSING=ON, $

Generated Access File

SEGNAME=N29004, TABLENAME=qatst.R729999D.N29004, CONNECTION=IBISYBASE, KEYS=0, $

Reference: Mapping Sybase IQ Table Comments Into a Synonym

When a synonym is created, the adapter picks up comments from a Sybase IQ database table and places them in the synonym:

- Sybase IQ Comment on Table maps to REMARKS in the Master File.
- Sybase IQ Comment on Field maps to DESCRIPTION in the Master File.

Reference: Access File Keywords

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the Sybase table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLENAME=[owner.]table</td>
</tr>
</tbody>
</table>
| CONNECTION | Indicates a previously declared connection. The syntax is: CONNECTION=connection
CONNECTION='' indicates access to the local Sybase database server. Absence of the CONNECTION attribute indicates access to the default database server. |
<table>
<thead>
<tr>
<th><strong>Keyword</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first n fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>KEYFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td>IXFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td>AUTO</td>
<td>Set to Yes to enable auto-incrementing.</td>
</tr>
<tr>
<td>INCREMENT</td>
<td>Initial value in the incrementing sequence.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>Increment interval.</td>
</tr>
<tr>
<td>INDEX_UNIQUE</td>
<td>Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).</td>
</tr>
<tr>
<td>INDEX_COLUMNS</td>
<td></td>
</tr>
<tr>
<td>INDEX_ORDER</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.
**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Accessing Different Databases on the Same Sybase Server**

When the server connects to Sybase, it uses a primary authorization ID. This ID is associated with a default database on the server. To access tables in another database, you must specify a fully qualified name as follows:

`database.owner.table`
This fully qualified name can be used in the SQL request. It must be used in the CREATE SYNONYM command for a table in a database other than the default associated with the connected primary authorization ID. If you are allowing access to multiple databases on the same Sybase Server, the user ID specified in the SET CONNECTION_ATTRIBUTES command must have authority to access the database, as well as the tables within the database. This can be achieved by using the Sybase stored procedure sp_adduser and the SQL GRANT statement. For more information, see the Sybase SQL Reference manual.

**Sybase Data Type Support**

**Reference:**
Sybase Data Type Support for Unicode

The following tables describe how the server maps Sybase ASE and IQ data types.

<table>
<thead>
<tr>
<th>Sybase ASE and IQ Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Date-Time Data Types</strong></td>

</tr>
<tr>
<td>Sybase ASE and IQ Data Type</td>
<td>Remarks</td>
<td>LONGCHAR ALPHA</td>
<td>LONGCHAR TEXT</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------</td>
<td>---------------</td>
<td>---------------</td>
</tr>
</tbody>
</table>
| VARBINARY (n)              | **ASE**: n is an integer between 1 and the largest integer supported by the database.  
**IQ**: n is an integer between 1 and 255,  
m = 2 * n. | AmV | TX50 |
| CHAR (n)                    | **ASE**: n is an integer between 1 and the largest integer supported by the database.  
**IQ**: n is an integer between 1 and 32767. | An | TX50 |
| VARCHAR (n)                 | **ASE**: n is an integer between 1 and the largest integer supported by the database.  
**IQ**: n is an integer between 1 and 32767. | An | TX50 |
| NCHAR (n)                   | **ASE only**: n is an integer between 1 and the largest integer supported by the database. | An | TX50 |
| NVARCHAR (n)                | **ASE only**: n is an integer between 1 and the largest integer supported by the database. | An | TX50 |

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB data types.

**Reference:** Sybase Data Type Support for Unicode

The following table describes how the Unicode server maps Character data types. The server operates in character semantic when configured for Unicode. The LONGCHAR setting does not affect mapping in this case.
### Controlling the Mapping of Large Character Data Types

**How to:**
- Control the Mapping of Large Character Data Types (Sybase ASE)
- Control the Mapping of Large Character Data Types (Sybase IQ)

**Reference:**
- Sybase ASE: Mapping of Large Character Data Types
- Sybase IQ: Mapping of Large Character Data Types

The SET parameter CONVERSION LONGCHAR controls the mapping of supported Sybase data types listed below. By default, the server maps these data types as alphanumeric (A). The server data type A supports a maximum of 4096 characters for TABLE/MODIFY and 32768 characters for API applications.

<table>
<thead>
<tr>
<th>Sybase ASE and IQ Data Type</th>

<td>$n$ is an integer between 1 and 255, $m = 2 \times n$</td>
<td>AmV</td>
<td>TX50</td>
</tr>
</tbody>
</table>

### Syntax: How to Control the Mapping of Large Character Data Types (Sybase ASE)

```sql
ENGINE SQLSYB SET CONVERSION LONGCHAR {ALPHA|TEXT|BLOB}
```

Where:

- **SQLSYB**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **ALPHA**
  - Maps the Sybase data types TEXT, BINARY, and VARBINARY as alphanumeric (A). ALPHA is the default value.

- **TEXT**
  - Maps the Sybase data types TEXT, BINARY, and VARBINARY as text (TX). Use this value for WebFOCUS applications.

- **BLOB**
  - For UNIX, Windows, OpenVMS, and IBM i, is identical to ALPHA. That is, it maps the Sybase data types TEXT, BINARY, and VARBINARY as alphanumeric (A).
  - For z/OS, maps the Sybase data types TEXT, BINARY, and VARBINARY as binary large object (BLOB).
**Reference:**  Sybase IQ: Mapping of Large Character Data Types

The following table lists data type mappings based on the value of LONGCHAR:

<table>
<thead>
<tr>
<th>Sybase IQ Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR BLOB</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>USAGE</td>
<td>ACTUAL</td>
<td>USAGE</td>
</tr>
<tr>
<td>BINARY (n)</td>
<td>$n$ is an integer between 1 and 255 $m = 2 \times n$</td>
<td>$Am$</td>
<td>$Am$</td>
<td>BLOB</td>
</tr>
<tr>
<td>VARBINARY (n)</td>
<td>$n$ is an integer between 1 and 255 $m = 2 \times n$</td>
<td>$AmV$</td>
<td>$AmV$</td>
<td>BLOB</td>
</tr>
</tbody>
</table>

**Syntax:**  How to Control the Mapping of Large Character Data Types (Sybase IQ)

```sql
ENGINE SQLSYB SET CONVERSION LONGCHAR {ALPHA | TEXT | BLOB}
```

where:

**SQLSYB**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ALPHA**

Maps the Sybase data types CHAR, VARCHAR, BINARY, and VARBINARY as alphanumeric (A). ALPHA is the default value.

**TEXT**

Maps the Sybase data types CHAR, NCHAR, VARCHAR, BINARY, and VARBINARY as text (TX). Use this value for WebFOCUS applications.

**BLOB**

Maps the Sybase data types CHAR, VARCHAR, BINARY, and VARBINARY as BLOB.
Controlling the Mapping of Variable-Length Data Types

**How to:**
Control the Mapping of Variable-Length Data Types (Sybase ASE)
Control the Mapping of Variable-Length Data Types (Sybase IQ)

**Reference:**
Sybase ASE: Mapping of Variable-Length Data Types
Sybase IQ: Mapping of Variable-Length Data Types

For Sybase ASE, the SET parameter VARCHAR controls the mapping of the Sybase data types VARCHAR, VARCHAR2, and NVARCHAR2. By default, the server maps these data types as variable character (AnV).

For Sybase IQ, the SET parameter VARCHAR controls the mapping of the Sybase data types VARCHAR and VARBINARY. By default, the server maps these data types as variable character (AnV).

**Reference:**  Sybase ASE: Mapping of Variable-Length Data Types

The following table lists data type mappings based on the value of VARCHAR:

<table>
<thead>
<tr>
<th>Sybase ASE Data Type</th>
<th>Remarks</th>
<th>VARCHAR ON</th>
<th>VARCHAR OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>USAGE</td>
<td>ACTUAL</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>( n ) is an integer between 1 and 255</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>NVARCHAR (n)</td>
<td>( n ) is an integer between 1 and 255</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>VARBINARY (n)</td>
<td>( n ) is an integer between 1 and 255m = 2 * n</td>
<td>AmV</td>
<td>AmV</td>
</tr>
</tbody>
</table>

**Syntax:**  How to Control the Mapping of Variable-Length Data Types (Sybase ASE)

```sql
ENGINE SQLSYB SET VARCHAR {ON|OFF}
```
where:

**SQLSYB**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Maps the Sybase data types VARCHAR, VARCHAR2, and NVARCHAR2 as variable-length alphanumeric (AnV). This is required for Unicode environments. ON is the default value.

**OFF**

Maps the Sybase data types VARCHAR, VARCHAR2, and NVARCHAR2 as alphanumeric (A).

**Reference: Sybase IQ: Mapping of Variable-Length Data Types**

The following table lists data type mappings based on the value of VARCHAR:

<table>
<thead>
<tr>
<th>Sybase IQ Data Type</th>
<th>Remarks</th>
<th>VARCHAR ON</th>
<th>VARCHAR OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>USAGE</td>
<td>ACTUAL</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>$n$ is an integer between 1 and 255</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>VARBINARY (n)</td>
<td>$n$ is an integer between 1 and 255 $m = 2 \times n$</td>
<td>AmV</td>
<td>AmV</td>
</tr>
</tbody>
</table>

**Syntax: How to Control the Mapping of Variable-Length Data Types (Sybase IQ)**

ENGINE SQLSYB SET VARCHAR {ON|OFF}

where:

**SQLSYB**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Maps the Sybase data types VARCHAR and VARBINARY as variable-length alphanumeric (AnV). ON is the default value.
Trailing Blanks in SQL Expressions

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

ENGINE SQLSYB SET TRIM_LITERALS ON

is available to ensure backward compatibility.

Changing the Precision and Scale of Numeric Columns

How to:
Override the Default Precision and Scale

Example:
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

Syntax: How to Override the Default Precision and Scale

ENGINE SQLSYB SET CONVERSION RESET
ENGINE SQLSYB SET CONVERSION format RESET
ENGINE SQLSYB SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLSYB SET CONVERSION format [PRECISION MAX]

where:

SQLSYB

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
RESET

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

format

Is any valid format supported by the data source. Possible values are:

- **INTEGER** which indicates that the command applies only to INTEGER columns.
- **DECIMAL** which indicates that the command applies only to DECIMAL columns.
- **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.

- **FLOAT** which indicates that the command applies only to double-precision floating-point columns.

precision

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

scale

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

MAX

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th><strong>Data Type</strong></th>
<th><strong>MAX Precision</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>
Note: When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.

Example: Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

ENGINE SQLSYB SET CONVERSION INTEGER PRECISION 7

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

ENGINE SQLSYB SET CONVERSION FLOAT PRECISION 14 3

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

ENGINE SQLSYB SET CONVERSION INTEGER RESET

The following example shows how to set the precision and scale attributes for all fields to the defaults:

ENGINE SQLSYB SET CONVERSION RESET

Reporting Against a Sybase Stored Procedure

You can use a reporting tool, such as a SELECT statement or TABLE command, to execute Sybase stored procedures and report against a procedure’s output parameters and answer set. Among the benefits of this method of executing a stored procedure are:

- The retrieval of output parameters, OUT parameters, and INOUT parameters in OUT mode, as well as the answer set. (Other methods of invocation retrieve the answer set only.)
The ease with which you can process, format, and display output parameters and the answer set, using TABLE and other reporting tools.

To report against a stored procedure:

1. **Generate a synonym** for the stored procedure answer set, as described in *Generating a Synonym for a Stored Procedure* on page 2414.

2. **Create a report procedure**, as described in *Creating a Report Against a Stored Procedure* on page 2418.

3. **Run the report**. This executes the stored procedure and reports against any output parameters (OUT and INOUT in OUT mode), and any answer set fields, specified in the report.

**Note:** For Sybase IQ data, support for stored procedures began with the SYBIQ 12.7 ESD #4 release.

### Generating a Synonym for a Stored Procedure

**Reference:**

Synonym Creation Parameters for Stored Procedures

A synonym describes a stored procedure’s parameters and answer set.

An answer set’s structure may vary depending on the input parameter values that are provided when the procedure is executed. Therefore, you need to generate a separate synonym for each set of input parameter values that will be provided when the procedure is executed at run time. For example, if users may execute the stored procedure using three different sets of input parameter values, you need to generate three synonyms, one for each set of values. (Unless noted otherwise, "input parameters" refers to IN parameters and to INOUT parameters in IN mode.)

**There is an exception:** if you know the internal logic of the procedure, and are certain which range of input parameter values will generate each answer set structure returned by the procedure, you can create one synonym for each answer set structure, and for each synonym simply provide a representative set of the input parameter values necessary to return that answer set structure.

A synonym includes the following segments:

- **INPUT**, which describes any IN parameters and INOUT parameters in IN mode.
  
  If there are no IN parameters or INOUT parameters in IN mode, the segment describes a single dummy field.

- **OUTPUT**, which describes any OUT parameters and INOUT parameters in OUT mode.
If there are no OUT parameters or INOUT parameters in OUT mode, the segment is omitted.

- ANSWERSETn, one for each answer set.
  
  If there is no answer set, the segment is omitted.

**Reference:** Synonym Creation Parameters for Stored Procedures

<table>
<thead>

</tr>
<tr>
<td>Values</td>
<td>Select the check box for every parameter displayed for the specified procedure. Note the following before you enter parameter values: if the procedure you selected has input parameters (IN parameters and/or INOUT parameters in IN mode), you will be prompted to enter values for them. However, the need for an explicit Value entry depends on the logic of the procedure and the data structures it produces. Therefore, while you must check the parameter box, you may not need to enter a value. Follow these guidelines:</td>
</tr>
<tr>
<td></td>
<td>- Explicit input values (and separate synonyms) are required when input parameter values cause answer sets with different data structures, which vary depending on the input parameters provided.</td>
</tr>
<tr>
<td></td>
<td>- Explicit input values are not required when you know the procedure’s internal logic and are certain that it always produces the same data structure. In this situation, only one synonym needs to be created and you can leave the Value input blank for synonym-creation purposes.</td>
</tr>
<tr>
<td></td>
<td>If a Value is required, enter it without quotes. Any date, date-time, and timestamp parameters must have values entered in an ISO format. Specify the same input parameters that will be provided when the procedure is executed at run time if it is a procedure that requires explicit values.</td>
</tr>
</tbody>
</table>
Creating a Report Against a Stored Procedure

**How to:**

Report Against a Stored Procedure Using the TABLE Command
Report Against a Stored Procedure Using SELECT

You can report against a stored procedure answer set using the same facilities you use to report against a database table:

- **SQL SELECT statement.** For syntax, see *How to Report Against a Stored Procedure Using SELECT* on page 2419.

- **TABLE and GRAPH commands.** For syntax, see *How to Report Against a Stored Procedure Using the TABLE Command* on page 2418.

When joining from or to a stored procedure answer set, you can:

- **Join from** only OUTPUT and ANSWERSET segments in a host file.
- **Join to** only INPUT segments in a cross-referenced file.

**Syntax: **

**How to Report Against a Stored Procedure Using the TABLE Command**

To execute a stored procedure using the TABLE command, use the following syntax:

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
.
.
.
END
```

where:

- **synonym**
  
  Is the synonym of the stored procedure you want to execute.

- **parameter**
  
  Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.

  If the stored procedure does not require parameters, specify an asterisk (*). This displays a dummy segment, created when the synonym is generated, to satisfy the structure of the SELECT statement.
* Indicates that you want to display all indicated parameters, or that there are no required parameters.

**IF**

Is an IF or WHERE keyword. Use this to pass a value to an IN parameter or an INOUT parameter in IN mode.

**in-parameter**

Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

**Note:** The length of in-parameters cannot exceed 1000 characters if the adapter is configured for Unicode support.

**value**

Is the value you are passing to a parameter.

### Syntax: How to Report Against a Stored Procedure Using SELECT

**SQL**

```
SELECT [parameter [, parameter] ... | *] FROM synonym
[WHERE in-parameter = value]
```

**END**

where:

**synonym**

Is the synonym of the stored procedure that you want to execute.

**parameter**

Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, enter an asterisk (*) in the syntax. This displays a dummy segment, created during synonym generation, to satisfy the structure of the SELECT statement.

* Indicates that you want to display all indicated parameters, or that there are no required parameters.
WHERE

Is used to pass a value to an IN parameter or an INOUT parameter in IN mode.

You must specify the value of each parameter on a separate line.

in-parameter

Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

value

Is the value you are passing to a parameter.

Customizing the Sybase Environment

In this section:

- Activating NONBLOCK Mode
- Obtaining the Number of Rows Updated or Deleted
- Enabling Password Encryption for Sybase ASE and IQ

The Adapter for Sybase provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.

Activating NONBLOCK Mode

How to:

Activate NONBLOCK Mode

The Adapter for Sybase has the ability to issue calls in NONBLOCK mode. The default behavior is BLOCK mode.

This feature allows the adapter to react to a client request to cancel a query while the adapter is waiting on engine processing. This wait state usually occurs during SQL parsing, before the first row of an answer set is ready for delivery to the adapter or while waiting for access to an object that has been locked by another application.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
**Syntax:** How to Activate NONBLOCK Mode

```
ENGINE SQLSYB SET NONBLOCK {0|n}
```

where:

- **SQLSYB**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **n**
  
  Is a positive numeric number. 0 is the default value, which means that the adapter will operate in BLOCK mode. A value of 1 or greater activates the NONBLOCK calling and specifies the time, in seconds, that the adapter will wait between each time it checks to see if the:
  
  - [ ] Query has been executed.
  - [ ] Client application has requested the cancellation of a query.
  - [ ] Kill Session button on the Web Console is pressed.

**Note:** A value of 1 or 2 should be sufficient for normal operations.

**Obtaining the Number of Rows Updated or Deleted**

**How to:**

Obtain the Number of Rows Updated or Deleted

```
PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.
```

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:** How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLSYB SET PASSRECS {ON|OFF}
```

where:

- **SQLSYB**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.
ON

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Enabling Password Encryption for Sybase ASE and IQ

How to:

Enable Password Encryption (ASE and IQ)

You can control password encryption when the adapter connects to a Sybase ASE or Sybase IQ data source. By default, the password encryption is turned off. If you activate the PASSWORD_ENCRYPTION setting, all subsequent connections made by the Adapter for Sybase servers are affected.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. When the Change Settings pane opens, choose OFF, ON, or EXTENDED from the pull-down list next to the PASSWORD_ENCRYPTION option.

Syntax: How to Enable Password Encryption (ASE and IQ)

SQL SYB SET PASSWORD_ENCRYPTION {ON|EXTENDED|OFF}

where:

ON

Sets the connection property CS_SEC_ENCRYPTION. Use this setting when you are only configuring for connections to a Sybase ASE data source.

EXTENDED

Sets the connection property CS_SEC_EXTENDED_ENCRYPTION. Use this setting when you are only configuring for connections to a Sybase IQ data source or when you are configuring for connections to both Sybase ASE and Sybase IQ data sources.
The property CS_SEC_EXTENDED_ENCRYPTION is available starting with Sybase Open Client version 15 ESD #7. If this value is not available for the given client version (that is, a client version earlier than Sybase Open Client version 15 ESD #7), the error message FOC1811 will be produced at the time of the setting and at the time of a connection attempt. (Other possible errors that may occur if the user's version of Open Client is earlier than 15 ESD #7 include the following: SQLCODE IS 5; ct_con_props(): User API layer: external error: An illegal value of 9213 given for parameter property.)

Sybase IQ supports only CS_SEC_EXTENDED_ENCRYPTION. A Sybase error message will result if a connection to an IQ server is attempted with the value ON in effect: SQLCODE IS 4002; ASA Error -103: Invalid user ID or password.

OFF

Password encryption is disabled. OFF is the default setting.

Optimization Settings

In this section:

Optimizing Requests
Optimizing Requests Containing IF-THEN-ELSE Virtual Fields
Optimizing Requests to Pass Virtual Fields Defined as Constants
Specifying Block Size for Retrieval Processing

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

**How to:**
Optimize Requests

**Example:**
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

**Reference:**
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

```sql
SQL SQLSYB SET {OPTIMIZATION|SQLJOIN} setting
```

where:

**SQLSYB**

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**SQLJOIN**

Is a synonym for OPTIMIZATION.

**setting**

Is the optimization setting. Valid values are as follows:

**ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

**OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:**  **SQL Requests Passed to the RDBMS With Optimization OFF**

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```sql
SQL SQLSYB SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END

In a trace operation, you will see the following output:

(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
FROM 'USER1'.EMPINFO T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
SELECT T2.EID FROM 'USER1'.FUNDTRAN T2 WHERE (T2.EID = ?)
FOR FETCH ONLY;
```

**Example:**  **SQL Requests Passed to the RDBMS With Optimization ON**

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```sql
SQL SQLSYB SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.'EMPINFO' T1, 'USER1'.'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID, T1.LN
ORDER BY T2.EID, T1.LN;
```

**Reference: SQL Generation in Optimization Examples**

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:**

Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**

Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**

SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.
**Syntax:** How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLSYB SET OPTIFTHENELSE {ON | OFF}
```

where:

- **SQLSYB**
  Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

- **ON**
  Enables IF-THEN-ELSE optimization. This is the default.

- **OFF**
  Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
SQL SQLSYB SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') 
AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME 
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN',T1.'FN',T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' '))
         AND (T1.'DPT' = 'MIS'))));
```
Example: Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
SQL SQLSYB SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
     ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
     WHERE (((T1.'LN' = 'SMITH')));

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
     WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```sql
SQL SQLSYB SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
**Reference: SQL Limitations on Optimization of DEFINE Expressions**

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  
  \[ X = X + 1; \]

- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

**Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Optimizing Requests to Pass Virtual Fields Defined as Constants

Example:
Passing Numeric Constants
Passing a CHAR Constant
Passing CHAR and INTEGER Constants

A virtual field defined as a constant is passed directly to an SQL database engine (RDBMS) for optimized processing that takes advantage of RDBMS join, sort, and aggregation capabilities, thus reducing the volume of RDBMS-to-server communication and improving response time. (In prior releases, constants were not passed to the database engine, causing optimization to be turned off.)

Constants in the following formats are passed to the RDBMS: NUMERIC, CHAR, VARCHAR, CHAR/INTEGER combination, and DATE. (Note that a few formats are not passed to the RDBMS; these are CHAR and VARCHAR combination, TIME, and DATETIME.)

When valid constants are passed to an RDBMS engine, a report is calculated based on the defined value(s) and only the calculated subset of records is returned. The extent of data manipulation at the adapter level is limited, thereby improving performance.

Example: Passing Numeric Constants

DEFINE FILE SMIX87
INTEGERCONST/I4 = 5
REALCONST/D20.2 = -97995.38
NUMERICCONST/P13.4 = -92999.3647

TABLE FILE SMIX87
SUM INTEGERCONST REALCONST NUMERICCONST MAX.QUOT.FA01INTEGER
BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", SUM(5), SUM(-97995.38),
SUM(-92999.3647), MAX(T2."FA01INTEGER") FROM TMIX83A T2 GROUP
BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

Example: Passing a CHAR Constant

DEFINE FILE SMIX87
CHARCONST/A10 = '2N'
The following SQL is generated:

```sql
SELECT T2."FA02INTEGER", MAX('2N'), MIN(T3."FA02CHAR_15") FROM TMIX83A T2,TMIX86A T3 WHERE (T3."FA01INTEGER" = T2."FA01INTEGER") GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Example: Passing CHAR and INTEGER Constants**

```sql
DEFINE FILE SMIX87
  CHARCONST/A10 = '2N'
  INTEGERCONST/I4 = 5
TABLE FILE SMIX87
  SUM CHARCONST INTEGERCONST
  BY QUOT.FA02INTEGER
END

The following SQL is generated:

```sql
SELECT T2."FA02INTEGER", MAX('2N'), SUM(5) FROM TMIX83A T2
  GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Specifying Block Size for Retrieval Processing**

**How to:**
- Specify Block Size for Array Retrieval
- Specify Block Size for Insert Processing
- Suppress the Bulk Insert API

**Reference:**
- Bulk Insert API Behavior

The Adapter for Sybase supports array retrieval from result sets produced by executing SELECT queries or stored procedures. This technique substantially reduces network traffic and CPU utilization.

Using high values increases the efficiency of requests involving many rows, at the cost of higher virtual storage requirements. A value higher than 100 is not recommended because the increased efficiency it would provide is generally negligible.
Tip: You can change this setting manually or from the Web Console by clicking Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the right-click menu. The Change Settings pane opens.

Syntax: How to Specify Block Size for Array Retrieval
The block size for a SELECT request applies to TABLE FILE requests, MODIFY requests, MATCH requests, and DIRECT SQL SELECT statements.

ENGINE SQLSYB SET FETCHSIZE n

where:

SQLSYB
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n
Is the number of rows to be retrieved at once using array retrieval techniques. Accepted values are 1 to 5000. The default varies by adapter. If the result set contains a column that has to be processed as a CLOB or a BLOB, the FETCHSIZE value used for that result set is 1.

Syntax: How to Specify Block Size for Insert Processing
In combination with LOADONLY, the block size for an INSERT applies to MODIFY INCLUDE requests. INSERTSIZE is also supported for parameterized DIRECT SQL INSERT statements.

ENGINE SQLSYB SET INSERTSIZE n

where:

SQLSYB
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n
Is the number of rows to be inserted using array insert techniques. Accepted values are 1 to 5000. 1 is the default value. If the result set contains a column that has to be processed as a BLOB, the INSERTSIZE value used for that result set is 1.

Syntax: How to Suppress the Bulk Insert API

ENGINE SQLSYB SET FASTLOAD [ON|OFF]
where:

**SQLSYB**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Uses the Bulk Insert API. ON is the default.

**OFF**

Suppresses the use of the Bulk Insert API.

**Reference: Bulk Insert API Behavior**

You can use DataMigrator with the Bulk Insert API for Sybase.

With the Adapter for Sybase, the Bulk Insert API is used in LOADONLY mode when INSERTSIZE is greater than 1. INSERTSIZE determines how often the intermediate data flush is performed. Measurements show that intermediate flushes are necessary for optimal Sybase server performance. As a rule of thumb, the INSERTSIZE value should be from several thousand to several tens of thousand. Intermediate flushes cannot be rolled back.

When you suppress the Bulk Load API, the Adapter for Sybase resorts to array insert according to the specified INSERTSIZE.

Errors that occur during the load (such as duplication) can cause the batch of rows to be rejected as a whole.

**Calling a Sybase Stored Procedure Using SQL Passthru**

**How to:**

Call a Sybase Stored Procedure
Run an Unchained Sybase Stored Procedure

**Example:**

Sybase Stored Procedure

Sybase stored procedures are supported using SQL Passthru. These procedures need to be developed within Sybase using the CREATE PROCEDURE command. A Sybase stored procedure is in either chained or unchained transaction mode. To change the default CHAINED property, see *How to Run an Unchained Sybase Stored Procedure* on page 2434.
**Syntax:**  How to Call a Sybase Stored Procedure

The supported syntax to call a stored procedure is shown below. It is recommended that you use the syntax below instead of the previously supported CALLSYB syntax.

```sql
ENGINE SQLSYB
EX SAMPLE PARM1, PARM2, PARM3...;
TABLE ON TABLE PCHOLD
END
```

where:

- **SQLSYB**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**Example:**  Sybase Stored Procedure

```sql
CREATE PROCEDURE SAMPLE
AS
SELECT SSN5, LAST_NAME5, FIRST_NAME5, BIRTHDATE5, SEX5 FROM EDAQA.NF29005
GO
exec sp_procxmode 'PROC1', 'anymode'
GO
```

**Syntax:**  How to Run an Unchained Sybase Stored Procedure

Sybase ASE stored procedures may be in either chained or unchained transaction mode.

By default, the Adapters for Sybase run stored procedures in chained transaction mode. If you want to run an unchained Sybase stored procedure, you need to first set the adapter CHAINED property to OFF using the following command:

```sql
ENGINE SQLSYB SET CHAINED {OFF | ON};
END
```

where:

- **SQLSYB**
  
  Indicates the adapter ASE. You can omit this value if you had previously issued the SET SQLENGINE command.

- **OFF**
  
  Sets the adapter to unchained transaction mode.

- **ON**
  
  Sets the adapter to chained transaction mode.

  The adapter is in chained transaction mode by default.
You can issue this command in a server procedure (focexec) or in the server profile (edasprof).
Calling a Sybase Stored Procedure Using SQL Passthru
The Adapter for Teradata allows applications to access Teradata data sources. The adapter converts application requests into native Teradata statements and returns optimized answer sets to the requesting application.

Topics:
- Preparing the Teradata Environment
- Configuring the Adapter for Teradata
- Managing Teradata Metadata
- Reporting Against a Teradata Stored Procedure
- Customizing the Teradata Environment
- Optimization Settings
- Calling a Teradata Macro or Stored Procedure Using SQL Passthru
Preparing the Teradata Environment

**In this section:**
Configuring Teradata CLI for Unicode

**How to:**
Set Up the Environment on Microsoft Windows Using ODBC or CLI
Set Up the Environment on UNIX

To configure and use the ODBC or CLI Adapter for Teradata, the Teradata Client components must be installed and configured according to the *Teradata Tools and Utilities Installation Guide*. TeraGSS, ICU, and ODBC and/or CLI are required. The path to the ODBC or CLI libraries directory must be added to SYSTEM LIBRARY PATH prior to starting the server.

If you are using the z/OS server, the Teradata Channel-Attached CLI needs to be installed. Use the Web Console to configure the Teradata Adapter.

**Procedure:  How to Set Up the Environment on Microsoft Windows Using ODBC or CLI**
On Microsoft Windows, the Teradata environment is set up during the installation of the product.

**Procedure:  How to Set Up the Environment on UNIX**
You can access Teradata using the optional UNIX environment variable, ODBCINI. The ODBCINI variable points to the absolute path of the .odbc.ini file.

For example:

```
ODBCINI=/usr/odbc/.odbc.ini
export ODBCINI
```

**Note:** You must not use ODBCINI, if the $HOME directory contains the .odbc.ini file.

**Configuring Teradata CLI for Unicode**
The Teradata CLI adapter supports Unicode UTF8 format if:

- The Teradata CLI client components are part of release TTU12.0 or higher.
- The Teradata database is release 12.0 or higher and appropriate language support was enabled during the sysinit process.

Contact your DBA to determine whether international language support has been enabled in your Teradata system and/or consult the Teradata documentation for details about International Character Set Support.
Note that, at the present time, when Unicode is enabled the length of a Teradata Column Name and/or TITLE cannot exceed 21 characters.

Configuring the Adapter for Teradata

In this section:
- Declaring Connection Attributes
- Overriding the Default Connection
- Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

How to:
- Declare Connection Attributes
- Declare Connection Attributes Manually

Example:
- Declaring Connection Attributes

Reference:
- Connection Attributes for Teradata
- Updating the Connection String for Teradata

In order to connect to a Teradata database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).
You can declare connections to more than one Teradata database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the Teradata Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**.
   - or
   - From the Data Management Console, expand the **Adapters** folder.
   The Adapters folder opens.

2. Expand the **Available** folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select **Configure**.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click **Configure**. The configured adapter is added to the Adapters list in the navigation pane.
Reference: Connection Attributes for Teradata

The Teradata adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Note that the release numbers on the Web Console for DBMS Add and DBMS Change panes refer to the Teradata ODBC driver, not the Teradata DBMS release.

Connection Name

This is the logical name used to identify this particular set of connection attributes.

Datasource or Server

Valid Teradata data source name (DSN). There is no default DSN; you must enter a value.

For the ODBC interface, this DSN name should match the User, System, or File DSN configured in the ODBC Administrator on Windows or the DSN entry in the $HOME/.odbc.ini file on UNIX.

For the CLI interface, this field is labeled SERVER and requires a valid Teradata TDP value. On Windows and UNIX, this is the value of i_dbcpath in the clispb.dat file. The default is DBC or <default>. This value may also be derived from the host file entry for the TD server. For example, if the host file contains td13cop1, then the server value will be td13. Refer to the Teradata Tools and Utilities documentation for details.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- Explicit. The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- Password Passthru. The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.
If you wish to create a new profile, either a user profile (`user.prf`) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (`edasprof`).

**Syntax:**

**How to Declare Connection Attributes Manually**

```sql
ENGINE SQLDBC SET CONNECTION_ATTRIBUTES {connection DSN_name|Server} /userid,password
```

where:

**SQLDBC**

Indicates the adapter. You can omit this value if you previously issued the `SET SQLENGINE` command.

**connection**

This is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between `connection` and `DSN_name`.

**DSN_name**

*For the Adapter for Teradata ODBC*, this is the Teradata Data Source Name (DSN) you wish to access. It must match an entry in the `odbc.ini` file.

**Server**

*For the Adapter for Teradata CLI*, this is the Teradata Director Program number (TDPn), where `n` is the number. This is the value of `i_dbcpath` in the `clispb.dat` file.

**userid**

Is the primary authorization ID by which you are known to Teradata.

**password**

Is the password associated with the primary authorization ID.

**Example:**

**Declaring Connection Attributes**

The following `SET CONNECTION_ATTRIBUTES` command connects to the Teradata database server named `SAMPLESERVER` with an explicit user ID (`MYUSER`) and password (`PASS`). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```sql
ENGINE SQLDBC SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS
```
**Reference: Updating the Connection String for Teradata**

The syntax for the `CONNECTION_ATTRIBUTES` command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing `CONNECTION_ATTRIBUTES` commands.

The Web Console Migrate option migrates your server settings to the newer release. To access this option, select *Workspace*, then *Configuration/Monitor* from the menu bar. Right-click *Migrate* from the *Server* folder in the navigation pane, and select *Configure*. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the *Migrate* button. This is the recommended approach.

If you choose *not* to use the Migrate option, please note the following information:

- **Connection names declared.**
- **If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.**
- **If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute `CONNECTION=value`.

For example, suppose that prior 7.6.1 the connection was defined as:

```
ENGINE SQLDBC SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
```

When synonyms based on objects stored in this DSN_A are created, the Access Files contain the following description:

```
CONNECTION=DSN_A
```

If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

```
ENGINE SQLDBC SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
```
Overriding the Default Connection

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:**

**How to Change the Default Connection**

`ENGINE SQLDBC SET DEFAULT_CONNECTION connection`

where:

- **SQLDBC**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

  **FOC1671, Command out of sequence**

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  **FOC1671, Command out of sequence.**

**Example:**

**Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

`ENGINE SQLDBC SET DEFAULT_CONNECTION SAMPLENAME`
Controlling the Connection Scope

**How to:**
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:**
How to Control the Connection Scope

```sql
ENGINE SQLDBC SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

- **SQLDBC**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **FIN**
  Disconnects automatically only after the session has been terminated. FIN is the default value.

- **COMMAND**
  Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

- **COMMIT**
  Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing Teradata Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, create a synonym that describes the data source's structure and the server mapping of the Teradata data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each Teradata table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source's location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.
Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server’s metadata.

Note that creating a synonym for a stored procedure is described with reporting against a stored procedure, in Generating a Synonym for a Stored Procedure on page 2464.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.

2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.
   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.
Synonym Creation Parameters for Teradata

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters ("," or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (\%) as needed at the beginning and/or end of the string. For example, enter: ABC\% to select tables or views whose owner/schema begin with the letters ABC; \%ABC to select tables or views whose owner/schema end with the letters ABC; \%ABC\% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (\%) as needed at the beginning and/or end of the string. For example, enter: ABC\% to select all objects whose names begin with the letters ABC; \%ABC to select all whose names end with the letters ABC; \%ABC\% to select all whose names contain the letters ABC at the beginning, middle, or end.

**Location of External SQL Scripts**

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.
In the **Document Extension** field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the **Base Location** field, enter:
  
  `/QSYS.LIB/MLIBRARY.LIB/MYSRC.FILE`

- The **Document Extension** is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

`DATASET=/ul/home2/apps/report3.sql`

When a WebFOCUS report is created, the SQL Query is used to access data.

### Cardinality

Select the **Cardinality** check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

### With foreign key

Select the **With foreign key** check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

### Dynamic columns

To specify that the Master File created for the synonym should not contain column information, select the **Dynamic columns** check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.
For Subquery

Only available when External SQL Scripts is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Teradata Data Type Support on page 2454.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Type

The object type (Table, View, and so on).
Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Teradata synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

FILE=DIVISION, SUFFIX=SQLDBC ,$
SENAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON ,$

Generated Access File nf29004.acx

SENAME=SEG1_4, TABLENAME=EDAQA.NF29004,
CONNECTION=DSN_A, KEYS=1, WRITE=YES ,$

Reference: Mapping Teradata Comments into a Synonym

When you generate a synonym for a Teradata table, the adapter maps each:

- Teradata table comment from the Teradata data dictionary to a Remark attribute in the Master File of the synonym.
- Teradata column comment from the Teradata data dictionary to a Description attribute in the Master File of the synonym.

Reference: Access File Keywords

This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SENAME</td>
<td>Value must be identical to the SENAME value in the Master File.</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Name of the table or view. This value can include a location or owner name as follows:</td>
</tr>
<tr>
<td></td>
<td>TABLENAME=[location.][owner.]tablename</td>
</tr>
<tr>
<td><strong>Keyword</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| CONNECTION   | Indicates a previously declared connection. The syntax is:  
CONNECTION=connection                                                                 |
| KEYS         | Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first \( n \) fields in the Master File segment. |
| WRITE        | Specifies whether write operations are allowed against the table.                                                                                |
| KEYFLD, IXFLD| Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.  
- KEYFLD is the FIELDNAME of the common column from the parent table.  
- IXFLD is the FIELDNAME of the common column from the related table.  
KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.  
**Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently. |
| AUTO_INCREMENT| Set to Yes to enable auto-incrementing.                                                                                                          |
| START        | Initial value in the incrementing sequence.                                                                                                       |
| INCREMENT    | Increment interval.                                                                                                                            |
| INDEX_NAME, INDEX_UNIQUE, INDEX_COLUMNS, INDEX_ORDER | Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).                                               |
Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
</tbody>
</table>
### Data Management

Followed by these options, if applicable:

**Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)

**Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted.

**Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values.

**Reorganize.** Recreates the data source table preserving original data.

**Note:** This option is not available in the Web Console.

### Impact Analysis

Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS* manual for details about Impact Analysis reports.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

### Teradata Data Type Support

The following tables describe how the server maps Teradata data types.
### Date-Time Data Types

<table>
<thead>
<tr>
<th>Teradata Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>YYMD</td>
<td>DATE</td>
</tr>
<tr>
<td>TIME</td>
<td>HHISsm</td>
<td>HHISsm</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>HYYMdm</td>
<td>HYYMdm</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>An</td>
<td>An</td>
</tr>
</tbody>
</table>

The operation with different Teradata TIME formats depends on DateTimeFormat setting in the data source part of the $HOME/.odbc.ini file. The adapter requires DateTimeFormat=IAI.

Neither the ODBC nor the CLI interface supports the integer format of TIME (I). Only the ANSI format of TIME (AT) is supported.

### Numeric Data Types

<table>
<thead>
<tr>
<th>Teradata Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>I6</td>
<td>I4</td>
</tr>
<tr>
<td>INTEGER</td>
<td>I11</td>
<td>I4</td>
</tr>
<tr>
<td>BYTEINT</td>
<td>I6</td>
<td>I4</td>
</tr>
<tr>
<td>Teradata Data Type</td>
<td>Server Data Type</td>
<td>Remarks</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td>BIGINT</td>
<td>P20</td>
<td>P10</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DECIMAL(n,m)</td>
<td>Pp.s</td>
<td>Pk</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A precision $n$ is an integer between 1 and 38. And a scale $m$ is an integer between 0 and $n$. The Teradata default DECIMAL is (5,0), which is mapped as P6, P8.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>If $n$ is less than or equal to 31, then $p$ is between 3 and 33, $p = n + 2$ and $s = m$.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>If $n$ is greater than 31, then $p$ is 33 and $k$ is 16.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Note that a Teradata numeric value longer than 31 digits is not supported. Such values contribute to an overflow condition and will be displayed as MISSING in a report.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Server Data Type

<table>
<thead>
<tr>
<th>Teradata Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMBER(n,m)</td>
<td>Pp.s</td>
<td>Pk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A precision $n$ is an integer between 1 and 38. And a scale $m$ is an integer between 0 and $n$.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If $n$ is less than or equal to 31, then $p$ is between 3 and 33, $p=n+2$ and $s=m$.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If $n$ is greater than 31, then $p$ is 33 and $k$ is 16.</td>
</tr>
<tr>
<td></td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When $n$ is omitted, or specified as a wild card (*).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note that a Teradata numeric value longer than 31 digits is not supported. Such values contribute to an overflow condition and will be displayed as MISSING in a report.</td>
</tr>
<tr>
<td>FLOAT</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 bytes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Range: $-2 \times 10^{307}$ to $2 \times 10^{308}$.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Same as REAL or DOUBLE PRECISION.</td>
</tr>
</tbody>
</table>

### LOB Data Types

<table>
<thead>
<tr>
<th>Teradata Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOB</td>
<td>TX50</td>
<td>TX</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Supported if Teradata and TTU versions are 13.10 or higher.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ODBC property UseNativeLOBSupport=Yes has to be set.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Read/Write functionality is supported for ODBC interface and only Read is supported for CLI.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>CLOB can not be used in the predicate in the WHERE-clause.</td>
</tr>
<tr>
<td>BLOB</td>
<td>TX50</td>
<td>BLOB</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Supported if Teradata and TTU versions are 13.10 or higher.</td>
</tr>
</tbody>
</table>
The following table lists how the non-Unicode server maps Character data types. This mapping can be changed based on the value of LONGCHAR. The default value is ALPHA. For more information, see *Controlling the Mapping of Large Character Data Types* on page 2459.

<table>
<thead>
<tr>
<th>Teradata Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>USAGE</td>
<td>ACTUAL</td>
</tr>
<tr>
<td>CHAR</td>
<td>An n is an integer between 1 and 256.</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td></td>
<td>An n is an integer between 257 and 32000.</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>An n is an integer between 1 and 256.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td></td>
<td>An n is an integer between 257 and 32000.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td>LONG VARCHAR (n)</td>
<td>An n is an integer between 1 and 256.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
<tr>
<td></td>
<td>An n is an integer between 257 and 64000. The server supports up to 32767 bytes. All data exceeding 32K will be truncated.</td>
<td>AnV</td>
<td>AnV</td>
</tr>
</tbody>
</table>

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.

**Data Type Support for Unicode**

The following table describes how the Unicode server maps Character data types. The server operates in character semantic when configured for Unicode. The LONGCHAR does not affect mapping in this case.

<table>
<thead>
<tr>
<th>Teradata Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(n)</td>
<td>AnV</td>
<td>AnV</td>
</tr>
</tbody>
</table>
Controlling the Mapping of Large Character Data Types

**How to:**
Control the Mapping of Large Character Data Types

The SET parameter CONVERSION LONGCHAR controls the mapping of supported Teradata data types listed below. By default, the server maps these data types as alphanumeric (A). The server data type A supports a maximum of 4096 characters for TABLE/MODIFY and 32768 characters for API applications.

**Syntax:**

```
ENGINE SQLDBC SET CONVERSION LONGCHAR {ALPHA|TEXT|BLOB}
```

where:

- **SQLDBC**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **ALPHA**
  Maps the Teradata data types CHAR, VARCHAR, and LONG VARCHAR as alphanumeric (A). ALPHA is the default value when the synonym is created manually.

- **TEXT**
  Maps the Teradata data types data types CHAR, VARCHAR, and LONG VARCHAR as text (TX). Use this value for WebFOCUS applications. TEXT is the default value when the synonym is created from the Web Console.

- **BLOB**
  For UNIX, Windows, OpenVMS, and IBM i, is identical to ALPHA. That is, it maps the Teradata data types CHAR, VARCHAR, and LONG VARCHAR as alphanumeric (A).
  
  For z/OS, maps the Teradata data types CHAR, VARCHAR, and LONG VARCHAR as binary large object (BLOB).
Controlling the Mapping of Variable-Length Data Types

**How to:**
Control the Mapping of Variable-Length Data Types

The SET parameter VARCHAR controls the mapping of the Teradata data type VARCHAR. By default, the server maps this data type as variable character (AnV).

The following table lists data type mappings based on the value of VARCHAR:

<table>
<thead>
<tr>
<th>Teradata Data Type</th>
<th>Remarks</th>
<th>VARCHAR ON</th>
<th>VARCHAR OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR (n)</td>
<td>n is an integer between 1 and 4000</td>
<td>AnV</td>
<td>An</td>
</tr>
<tr>
<td></td>
<td></td>
<td>AnV</td>
<td>An</td>
</tr>
</tbody>
</table>

**Syntax:**

**How to Control the Mapping of Variable-Length Data Types**

```
ENGINE SQLDBC SET VARCHAR {ON|OFF}
```

where:

**SQLDBC**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Maps the Teradata data type VARCHAR as variable-length alphanumeric (AnV). ON is the default value.

**OFF**

Maps the Teradata data type VARCHAR as alphanumeric (A).

**Trailing Blanks in SQL Expressions**

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

```
ENGINE SQLDBC SET TRIM_LITERALS ON
```

is available to ensure backward compatibility.
Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**
**How to Override the Default Precision and Scale**

```
ENGINE SQLDBC SET CONVERSION RESET
ENGINE SQLDBC SET CONVERSION format RESET
ENGINE SQLDBC SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLDBC SET CONVERSION format [PRECISION MAX]
```

where:

**SQLDBC**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**
Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**
Is any valid format supported by the data source. Possible values are:

- **INTEGER** which indicates that the command applies only to INTEGER columns.
- **DECIMAL** which indicates that the command applies only to DECIMAL columns.
- **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```
ENGINE SQLEDBC SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```
ENGINE SQLEDBC SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```
ENGINE SQLEDBC SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```
ENGINE SQLEDBC SET CONVERSION RESET
```

**Reporting Against a Teradata Stored Procedure**

**In this section:**
- Generating a Synonym for a Stored Procedure
- Creating a Report Against a Stored Procedure

You can use a reporting tool, such as a SELECT statement or TABLE command, to execute Teradata stored procedures and report against a procedure output parameters and answer set. Among the benefits of this method of executing a stored procedure are:

- The retrieval of output parameters, OUT parameters, and INOUT parameters in OUT mode, as well as the answer set. (Other methods of invocation retrieve the answer set only.)
- The ease with which you can process, format, and display output parameters and the answer set, using TABLE and other reporting tools.

To report against a stored procedure:

1. **Generate a synonym** for the stored procedure answer set, as described in *Generating a Synonym for a Stored Procedure* on page 2464.

2. **Create a report procedure**, as described in *Creating a Report Against a Stored Procedure* on page 2466.

3. **Run the report.** This executes the stored procedure and reports against any output parameters (OUT and INOUT in OUT mode), and any answer set fields, specified in the report.
This is supported for the Teradata ODBC interface only.

**Generating a Synonym for a Stored Procedure**

**Reference:**

Synonym Creation Parameters for Stored Procedures

A synonym describes stored procedure parameters and answer set. An answer set's structure may vary depending on the input parameter values that are provided when the procedure is executed. Therefore, you need to generate a separate synonym for each set of input parameter values that will be provided when the procedure is executed at run time. For example, if users may execute the stored procedure using three different sets of input parameter values, you need to generate three synonyms, one for each set of values. (Unless noted otherwise, "input parameters" refers to IN parameters and to INOUT parameters in IN mode.)

**There is an exception:** if you know the procedure's internal logic, and are certain which range of input parameter values will generate each answer set structure returned by the procedure, you can create one synonym for each answer set structure, and for each synonym simply provide a representative set of the input parameter values necessary to return that answer set structure.

A synonym includes the following segments:

- **INPUT**, which describes any IN parameters and INOUT parameters in IN mode.
  
  If there are no IN parameters or INOUT parameters in IN mode, the segment describes a single dummy field.

- **OUTPUT**, which describes any OUT parameters and INOUT parameters in OUT mode.
  
  If there are no OUT parameters or INOUT parameters in OUT mode, the segment is omitted.

- **ANSWERSETn**, one for each answer set.
  
  If there is no answer set, the segment is omitted.

**Reference:** Synonym Creation Parameters for Stored Procedures

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Select *Stored Procedures*. 
Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Select

Select a procedure. You may only select one procedure at a time since each procedure will require unique input in the Values box on the next synonym creation pane.

Name

The name of the synonym, which defaults to the stored procedure name.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have stored procedures with identical names, assign a prefix or a suffix to distinguish their corresponding synonyms. Note that the resulting synonym name cannot exceed 64 characters.

If all procedures have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.
For information about customizable mappings, see *Teradata Data Type Support* on page 2454.

**Values**

Select the check box for every parameter displayed for the specified procedure.

Note the following before you enter parameter values: if the procedure you selected has input parameters (IN parameters and/or INOUT parameters in IN mode), you will be prompted to enter values for them. However, the need for an explicit Value entry depends on the logic of the procedure and the data structures it produces. Therefore, while you must check the parameter box, you may not need to enter a value. Follow these guidelines:

- Explicit input values (and separate synonyms) are required when input parameter values cause answer sets with different data structures, which vary depending on the input parameters provided.

- Explicit input values are not required when you know the procedure’s internal logic and are certain that it always produces the same data structure. In this situation, only one synonym needs to be created and you can leave the Value input blank for synonym-creation purposes.

If a Value is required, enter it without quotes. Any date, date-time, and timestamp parameters must have values entered in an ISO format. Specify the same input parameters that will be provided when the procedure is executed at run time if it is a procedure that requires explicit values.

### Creating a Report Against a Stored Procedure

**How to:**

Report Against a Stored Procedure Using the TABLE Command

Report Against a Stored Procedure Using SELECT

You can report against a stored procedure’s answer set using the same facilities you use to report against a database table:

- **SQL SELECT statement.** For syntax, see *How to Report Against a Stored Procedure Using SELECT* on page 2468.

- **TABLE and GRAPH commands.** For syntax, see *How to Report Against a Stored Procedure Using the TABLE Command* on page 2467.

When joining from or to a stored procedure answer set, you can:

- **Join from** only OUTPUT and ANSWERSET segments in a host file.
Join to only INPUT segments in a cross-referenced file.

**Syntax:**

**How to Report Against a Stored Procedure Using the TABLE Command**

To execute a stored procedure using the TABLE command, use the following syntax:

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
.
.
.
END
```

where:

- **synonym**
  - Is the synonym of the stored procedure you want to execute.

- **parameter**
  - Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.
  - If the stored procedure does not require parameters, specify an asterisk (*). This displays a dummy segment, created when the synonym is generated, to satisfy the structure of the SELECT statement.

- *****
  - Indicates that you want to display all indicated parameters, or that there are no required parameters.

- **IF**
  - Is an IF or WHERE keyword. Use this to pass a value to an IN parameter or an INOUT parameter in IN mode.

- **in-parameter**
  - Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

**Note:** The length of in-parameters cannot exceed 1000 characters if the adapter is configured for Unicode support.

- **value**
  - Is the value you are passing to a parameter.
How to Report Against a Stored Procedure Using SELECT

Syntax:

SQL
SELECT [parameter [,parameter] ... | *] FROM synonym
[WHERE in-parameter = value]
.
.
.
END

where:

**synonym**

Is the synonym of the stored procedure that you want to execute.

**parameter**

Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, enter an asterisk (*) in the syntax. This displays a dummy segment, created during synonym generation, to satisfy the structure of the SELECT statement.

**\***

Indicates that you want to display all indicated parameters, or that there are no required parameters.

**WHERE**

Is used to pass a value to an IN parameter or an INOUT parameter in IN mode.

You must specify the value of each parameter on a separate line.

**in-parameter**

Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

**value**

Is the value you are passing to a parameter.
Customizing the Teradata Environment

The Adapter for Teradata provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.

Controlling the Column Heading in a Request

You can specify a column’s heading in a report using the Web Console. Alternatively, you can issue the SET COLNAME command.

Syntax: How to Control Column Headings Using a Command

ENGINE SQLDBC SET COLNAME {NAME|TITLE}

where:

SQLDBC
Indicates the adapter. You can omit this parameter value if you previously issued the SET SQLENGINE command.

NAME
If you specify the NAME option, the Teradata column name will be used as the column heading.

TITLE
If you specify the TITLE option, the name you provide is used as the column heading. TITLE is the default value.
Activating NONBLOCK Mode

How to:
Activate NONBLOCK Mode

The Adapter for Teradata has the ability to issue calls in NONBLOCK mode. The default behavior is BLOCK mode.

This feature allows the adapter to react to a client request to cancel a query while the adapter is waiting on engine processing. This wait state usually occurs during SQL parsing, before the first row of an answer set is ready for delivery to the adapter or while waiting for access to an object that has been locked by another application.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Activate NONBLOCK Mode

ENGINE SQLDBC SET NONBLOCK {0|n}

where:

SQLDBC

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n

Is a positive numeric number. 0 is the default value, which means that the adapter will operate in BLOCK mode. A value of 1 or greater activates the NONBLOCK calling and specifies the time, in seconds, that the adapter will wait between each time it checks to see if the:

- Query has been executed.
- Client application has requested the cancellation of a query.
- Kill Session button on the Web Console is pressed.

Note: A value of 1 or 2 should be sufficient for normal operations.
Obtaining the Number of Rows Updated or Deleted

**How to:**

Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

**How to Obtain the Number of Rows Updated or Deleted**

```sql
ENGINE SQLDBC SET PASSRECS {ON | OFF}
```

where:

- **SQLDBC**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **ON**
  Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

- **OFF**
  Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Setting the Transaction Mode Within a Teradata Connection

**How to:**

Set the Transaction Mode of a Teradata Connection

You can control a Teradata connection's transaction mode using the Web Console or by issuing a command.
Syntax: How to Set the Transaction Mode of a Teradata Connection

To set the transaction mode of a Teradata connection, issue the following command in any profile or in a procedure

```sql
SQL SQLDBC SET TRANSACTION [ANSI|BTET|DEFAULT]
```

where:

- **ANSI**
  - Sets the Teradata connection to the ANSI transaction mode. This is the default for a CLI connection.

- **BTET**
  - Sets the Teradata connection to the Teradata transaction mode (also known as the BTET transaction mode).

- **DEFAULT**
  - **For ODBC connections only.** Sets the Teradata connection to the Teradata system default transaction mode. This is the default for an ODBC connection.

For more information about how the Teradata system default is determined, see your Teradata documentation.

**Note:** The connection scope is different when setting the transaction mode for ODBC and CLI connections.

- **For an ODBC Connection:** The transaction mode can be set within an active connection. There is no needs to disconnect.

- **For a CLI Connection:** The transaction mode can be set only before the connection takes place. You must terminate the connection first using the SQL SQLDBC END SESSION command if you want to change the transaction mode for a CLI connection. Failure to do so will return the following warning:

  `(FOC1722) WARNING: COULD NOT SET TRANSACTION MODE`
Optimization Settings

In this section:
Optimizing Requests
Optimizing Requests Containing IF-THEN-ELSE Virtual Fields
Optimizing Requests to Pass Virtual Fields Defined as Constants
Specifying the Block Size for Insert Processing
Improving Efficiency With Aggregate Awareness
Optimizing Non-Equality WHERE-Based Left Outer Joins

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

Optimizing Requests

How to:
Optimize Requests

Example:
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

Reference:
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

SQL SQLDBC SET {OPTIMIZATION|SQLJOIN} setting
where:

SQLDBC

Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

SQLJOIN

Is a synonym for OPTIMIZATION.

setting

Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.

Both OPTIMIZATION settings produce the same report.

Example:  SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLDBC SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED

SELECT T1.EID, T1.LN, T1.DPT, T1.CSAL, T1.OJT
FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;

SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?) FOR FETCH ONLY;

**Example:**  **SQL Requests Passed to the RDBMS With Optimization ON**

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLDBC SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

AGGREGATION DONE ...

```
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID, T1.LN
ORDER BY T2.EID, T1.LN;
```

**Reference:**  **SQL Generation in Optimization Examples**

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.
Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

How to:
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

Example:
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

Reference:
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

SQL SQLDBC SET OPTIFTHENELSE {ON|OFF}

where:

SQLDBC
Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

ON
Enables IF-THEN-ELSE optimization. This is the default.

OFF
Disables IF-THEN-ELSE optimization.
There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
 SQL SQLDBC SET OPTIFTHENELSE ON
 DEFINE FILE EMPINFO
 DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
 END
 TABLE FILE EMPINFO
 PRINT DEPARTMENT LAST_NAME FIRST_NAME
 WHERE DEF1 EQ 1
 END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN',T1.'FN',T1.'DPT' FROM USER1.'EMPINFO' T1 WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' ')) AND (T1.'DPT' = 'MIS'))));
```

**Example:** Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
 SQL SQLDBC SET OPTIFTHENELSE ON
 DEFINE FILE EMPINFO
 DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2 ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
 END
 TABLE FILE EMPINFO
 SUM MAX.LAST_NAME IF DEF2 EQ 1
 END
```
The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
  WHERE (((T1.'LN' = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
  WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

**Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False**

```sql
SQL SQLDBC SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END
```

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```

**Reference: SQL Limitations on Optimization of DEFINE Expressions**

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  ```sql
  X=X+1;
  ```
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

**Note:** Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.

- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.

- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

  **Note:** FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.

- STATIC SQL.

- IF/WHERE DDNAME.

- Partial date selection.

**Optimizing Requests to Pass Virtual Fields Defined as Constants**

---

**Example:**

Passing Numeric Constants

Passing a CHAR Constant

Passing CHAR and INTEGER Constants

---

A virtual field defined as a constant is passed directly to an SQL database engine (RDBMS) for optimized processing that takes advantage of RDBMS join, sort, and aggregation capabilities, thus reducing the volume of RDBMS-to-server communication and improving response time. (In prior releases, constants were not passed to the database engine, causing optimization to be turned off.)

Constants in the following formats are passed to the RDBMS: NUMERIC, CHAR, VARCHAR, CHAR/INTEGER combination, and DATE. (Note that a few formats are not passed to the RDBMS; these are CHAR and VARCHAR combination, TIME, and DATETIME.)
When valid constants are passed to an RDBMS engine, a report is calculated based on the defined value(s) and only the calculated subset of records is returned. The extent of data manipulation at the adapter level is limited, thereby improving performance.

**Example: Passing Numeric Constants**

DEFINE FILE SMIX87
INTEGERCONST/I4 = 5
REALCONST/D20.2 = -97995.38
NUMERICCONST/P13.4 = -92999.3647

TABLE FILE SMIX87
  SUM INTEGERCONST REALCONST NUMERICCONST MAX.QUOT.FA01INTEGER
  BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", SUM(5), SUM(-97995.38),
   SUM(-92999.3647), MAX(T2."FA01INTEGER") FROM TMIX83A T2 GROUP
   BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

**Example: Passing a CHAR Constant**

DEFINE FILE SMIX87
CHARCONST/A10 = '2N'

TABLE FILE SMIX87
  SUM CHARCONST MIN.FA02CHAR_15
  BY QUOT.FA02INTEGER
END

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), MIN(T3."FA02CHAR_15") FROM
   TMIX83A T2,TMIX86A T3 WHERE (T3."FA01INTEGER" =
   T2."FA01INTEGER") GROUP BY T2."FA02INTEGER" ORDER BY
   T2."FA02INTEGER";
```

**Example: Passing CHAR and INTEGER Constants**

DEFINE FILE SMIX87
CHARCONST/A10 = '2N'
INTEGERCONST/I4 = 5

TABLE FILE SMIX87
  SUM CHARCONST INTEGERCONST
  BY QUOT.FA02INTEGER
END
The following SQL is generated:

```sql
SELECT T2."FA02INTEGER", MAX('2N'), SUM(5) FROM TMIX83A T2
GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

### Specifying the Block Size for Insert Processing

**How to:**

Specify the Block Size for Insert Processing

The Adapter for Teradata supports array insert if the release of Teradata Client is:

- **ODBC:** TTU13.10 or higher.
- **CLI:** TTU12.00 or higher.

This technique substantially reduces network traffic and CPU utilization.

Using high values increases the efficiency of requests involving many rows, at the cost of higher virtual storage requirements.

**Tip:** You can change this setting manually.

**Syntax:**

**How to Specify the Block Size for Insert Processing**

In combination with LOADONLY, the block size for an INSERT applies to MODIFY INCLUDE requests. INSERTSIZE is also supported for parameterized DIRECT SQL INSERT statements.

```sql
ENGINE SQLDBC SET INSERTSIZE n
```

where:

- **SQLDBC**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **n**
  Is the number of rows to be inserted using array insert techniques. Accepted values are 1 to 5,000. The default value is 1. If the result set contains a column that has to be processed as a LOB, the INSERTSIZE value used for that result set is 1.

### Improving Efficiency With Aggregate Awareness

Aggregate awareness substantially improves the efficiency of queries.

**Note:** For Teradata, aggregate awareness is handled internally. No adapter settings are required. However, the COLLECT STATISTICS command must be issued in Teradata.
Optimizing Non-Equality WHERE-Based Left Outer Joins

**How to:**
Specify a Conditional Left Outer JOIN

**Example:**
Optimizing a Non-Equality Left-Outer Join

**Reference:**
Conditions for WHERE-Based Outer Join Optimization

A left outer join selects all records from the host table and matches them with records from the cross-referenced table. When no matching records exist, the host record is still retained, and default values (blank or zero) are assigned to the cross-referenced fields. The adapter can optimize any WHERE-based left outer join command in which the conditional expression is supported by the RDBMS.

**Syntax:**  
How to Specify a Conditional Left Outer JOIN

```
JOIN LEFT_OUTER FILE hostfile AT hfld1 [TAG tag1]  
  [WITH hfld2]  
  TO {UNIQUE|MULTIPLE}  
  FILE crfile AT crfld [TAG tag2] [AS joinname]  
  [WHERE expression1;  
  [WHERE expression2;  
  ...]
END

where:

LEFT_OUTER

  Specifies a left outer join. If you do not specify the type of join in the JOIN command, the ALL parameter setting determines the type of join to perform.

hostfile

  Is the host Master File.

AT

  Links the correct parent segment or host to the correct child or cross-referenced segment. The field values used as the AT parameter are not used to cause the link. They are used as segment references.
hfld1

Is the field name in the host Master File whose segment will be joined to the cross-referenced data source. The field name must be at the lowest level segment in its data source that is referenced.

tag1

Is the optional tag name that is used as a unique qualifier for fields and aliases in the host data source.

WITH hfld2

Is a data source field with which to associate a DEFINE-based conditional JOIN. For a DEFINE-based conditional join, the KEEPDEFINES setting must be ON, and you must create the virtual fields before issuing the JOIN command.

MULTIPLE

Specifies a one-to-many relationship between from_file and to_file. Note that ALL is a synonym for MULTIPLE.

UNIQUE

Specifies a one-to-one relationship between hostfile and crfile. Note that ONE is a synonym for UNIQUE.

Note: Unique returns only one instance and, if there is no matching instance in the cross-referenced file, it supplies default values (blank for alphanumeric fields and zero for numeric fields).

The unique join is a WebFOCUS concept. The RDBMS makes no distinction between unique and non-unique situations; it always retrieves all matching rows from the cross-referenced file.

If the RDBMS processes a join that the request specifies as unique, and if there are, in fact, multiple corresponding rows in the cross-referenced file, the RDBMS returns all matching rows. If, instead, optimization is disabled so that WebFOCUS processes the join, a different report results because WebFOCUS, respecting the unique join concept, returns only one cross-referenced row for each host row.

crfile

Is the cross-referenced Master File.

crfld

Is the join field name in the cross-referenced Master File. It can be any field in the segment.
tag2
Is the optional tag name that is used as a unique qualifier for fields and aliases in the cross-referenced data source.

joinname
Is the name associated with the joined structure.

expression1, expression2
Are any expressions that are acceptable in a DEFINE FILE command. All fields used in the expressions must lie on a single path.

Reference: Conditions for WHERE-Based Outer Join Optimization

- In order for a WHERE-based left outer join to be optimized, the expressions must be optimizable for the RDBMS involved and at least one of the following conditions must be true:
  - The JOIN WHERE command contains at least one field1 EQ field2 predicate in which field1 is in table1 and field2 is in table2.
  - or
  - The right table has a key or a unique index that does not contain NULL data.
  - or
  - The right table contains at least one "NOT NULL" column that does not have a long data type (such as TEXT or IMAGE).

- The adapter SQLJOIN OUTER setting must be ON (the default).
Example: Optimizing a Non-Equality Left-Outer Join

The following request creates a left outer conditional join between two Teradata data sources and reports against the joined data sources. The STMTRACE is turned on in order to view the SQL generated for this request:

```sql
SET TRACEUSER = ON
SET TRACEOFF = ALL
SET TRACEON = STMTRACE//CLIENT
JOIN LEFT_OUTER FILE baseapp/EQUIP AT CARS
TO ALL FILE baseapp/CARREC AT CARC
WHERE CARS NE CARC;
END
TABLE FILE baseapp/EQUIP
PRINT CARS CARC STANDARD
BY MODEL
END
```

The WebFOCUS request is translated to a single Teradata SELECT statement that incorporates the left outer join, and the non-equality condition is passed to the RDBMS in the ON clause:

```sql
SELECT T1."CARS"(CHAR( 16)), T1."STANDARD"(CHAR( 40)), T2."CARC"(CHAR( 16)), T2."MODEL"(CHAR( 24)) FROM ( EQUIP T1
LEFT OUTER JOIN CARREC T2 ON (T1."CARS" <> T2."CARC") ) ORDER BY T2."MODEL";
```

Calling a Teradata Macro or Stored Procedure Using SQL Passthru

Example: Calling a Macro
Calling a Stored Procedure
Teradata Stored Procedure

SQL Passthru is supported for Teradata macros and stored procedures.

Macros need to be developed within Teradata using the CREATE or REPLACE MACRO command. Procedures need to be developed within Teradata using the CREATE PROCEDURE command.
You must call a macro in the same transaction mode in which it was compiled. For information about setting the transaction mode, see Setting the Transaction Mode Within a Teradata Connection on page 2471. To find out which transaction mode is currently in effect, issue the HELP session command:

```sql
SQL SQLDBC HELP SESSION;
TABLE FILE SQLOUT PRINT TRANSACTION_SEMANTICS
END
```

Before you can call a stored procedure or a macro, you must set the connection accordingly, either using the Web Console or by issuing the SET MACRO command

```sql
SQL SQLDBC SET MACRO [ON|OFF]
```

where:

- **ON** Enables one to call a macro. This is the default.
- **OFF** Enables one to call a stored procedure.

**Example: Calling a Macro**

This is an example of the syntax for calling a macro:

```sql
ENGINE SQLDBC
EX SAMPLE PARM1,PARM2,PARM3...;
TABLE FILE SQLOUT
END
```

**Example: Calling a Stored Procedure**

The supported syntax to call a stored procedure is shown below.

```sql
ENGINE SQLDBC
EX SAMPLE PARM1,PARM2,PARM3...;
TABLE FILE SQLOUT
END
```

When using the adapter with:

- **ODBC**, all scalar parameters (IN, OUT, and INOUT) are supported.
- **CLI**, scalar IN parameters, and INOUT parameters in IN mode, are supported.
**Example:**  **Teradata Stored Procedure**

```sql
CREATE OR REPLACE PACKAGE pack1 AS

  TYPE nfrectype IS RECORD (
    employee NF29005.EMPLOYEE_ID5%TYPE,
    ssn5 NF29005.SSN5%TYPE,
    l_name NF29005.LAST_NAME5%TYPE,
    f_name NF29005.FIRST_NAME5%TYPE,
    birthday NF29005.BIRTHDATE5%TYPE,
    salary NF29005.SALARY5%TYPE,
    joblevel NF29005.JOB_LEVEL5%TYPE);

  TYPE nfcurtype IS REF CURSOR RETURN nfrectype;

  PROCEDURE proc1(c_saltable IN OUT nfcurtype);

END pack1;
```

```sql
CREATE OR REPLACE PACKAGE BODY pack1 AS

  PROCEDURE proc1 (c_saltable IN OUT nfcurtype)
  IS
    BEGIN
      OPEN c_saltable FOR SELECT
      EMPLOYEE_ID5,SSN5,LAST_NAME5,FIRST_NAME5,BIRTHDATE5,
      SALARY5,JOB_LEVEL5 FROM NF29005;
      END proc1; -- end of procedure
  END pack1; -- end of package body
```

---

Adapter Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS

69. Using the Adapter for Teradata
Calling a Teradata Macro or Stored Procedure Using SQL Passthru
The Adapter for Transoft allows applications to access Transoft data sources. The adapter converts application requests into Transoft calls and returns optimized answer sets to the requesting application.

**Topics:**
- Preparing the Transoft Environment
- Configuring the Adapter for Transoft
- Managing Transoft Metadata
- Customizing the Transoft Environment
- Optimization Settings
Preparing the Transoft Environment

How to: Set Up the Environment on Windows and UNIX

In order to use the Adapter for Transoft, you must install the Transoft driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the Transoft Driver files by adding them to the environment variable CLASSPATH before server startup.
   
   For example, to set a UNIX or IBM i location for some JDBC Driver files to /usr/driver_files/mydriver.jar, issue the commands:
   
   ```
   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH
   ```
   
   Similarly, on Windows, you would issue the command:
   
   ```
   set CLASSPATH=c:\usr\driver_files\mydriver.jar;%CLASSPATH%
   ```
   
   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.
   
   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.
   
   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace
   
   ```
   edastart -show
   ```
   
   and check the special services section displays "JSCOM3 active".
   
   If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server's EDAPRINT. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the Server Installation manual.
Configuring the Adapter for Transoft

In this section:
Declaring Connection Attributes
Overriding the Default Connection
Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Example:
Declaring Connection Attributes

Reference:
Connection Attributes for Transoft

In order to connect to a Transoft data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one Transoft data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.
**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Adapters*.
   
   or

   From the Data Management Console, expand the *Adapters* folder.
   
   The Adapters folder opens.

2. Expand the *Available* folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.
   
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

**Reference: Connection Attributes for Transoft**

The Transoft adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**URL**

Location URL for the Transoft data source.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**Driver name**

Name for the Transoft JDBC driver.
For example: jdbc.transoft.Driver

See Transoft documentation for the specific driver release you are using.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Syntax:**

How to Declare Connection Attributes Manually

**ENGINE SQLTRN** SET CONNECTION_ATTRIBUTES connection

'URL'/userid,password

where:

**SQLTRN**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**

Is the connection name.

**URL**

Is the URL to the location of the Transoft data source.

**userid**

Is the primary authorization ID by which you are known to the target database.

**password**

Is the password associated with the primary authorization ID.

**Example:**

Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to a data source using the Transoft Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.
Note: Consult vendor documentation for the exact name, port, and path.

ENGINE SQLTRN SET CONNECTION_ATTRIBUTES CON1
'jdbc:transoft://hostname:7000/books.udd'

Overriding the Default Connection

How to:
Change the Default Connection

Example:
Selecting the Default Connection

If multiple connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

ENGINE SQLTRN SET DEFAULT_CONNECTION connection

where:

SQLTRN
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

collection
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

FOC1671, Command out of sequence

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

FOC1671, Command out of sequence.
**Example:**  **Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```sql
ENGINE SQLTRN SET DEFAULT_CONNECTION SAMPLENAME
```

**Controlling the Connection Scope**

**How to:**  
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:**  **How to Control the Connection Scope**

```sql
ENGINE SQLTRN SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

- **SQLTRN**
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **FIN**
  Disconnects automatically only after the session has been terminated. FIN is the default value.

- **COMMIT**
  Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing Transoft Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLTRN to identify the Adapter for Transoft.

Syntax: How to Identify the Adapter

FILE[NAME]=file, SUFFIX=SQLTRN [,,$]

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLTRN

Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using Transoft, you must locally install the RDBMS Transoft Driver.
The Server can access third-party database tables across the Transoft network. You must specify a URL for the data source and, possibly, a user ID and/or password for the database you are accessing. You can define these parameters in either the server global profile or in a user profile.

Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Sample Generated Synonym

**Reference:**
Synonym Creation Parameters for Transoft
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source’s location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server's metadata.

**Note:** If you are creating a synonym for a Transoft data source, you must first add the syntax SET SYNONYM=BASIC to the edasprof.prf file.

**Procedure:** **How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   The *Select adapter to configure or Select connection to create synonym* pane opens.

3. Click a connection for the configured adapter.
The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.
- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

**Reference:** Synonym Creation Parameters for Transoft

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
Object name. Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts
If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the Base Location field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the Document Name field, enter the file name with or without wild card characters.
- In the Document Extension field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the Base Location field, enter:
  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

  The Document Extension is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

`DATASET=/ul/home2/apps/report3.sql`

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality
Select the Cardinality check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
**With foreign key**

Select the *With foreign key* check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Customize data type mappings**

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support* on page 2504.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
Default Synonym Name
This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema
The user account that created the object or a collection of objects owned by a user.

Type
The object type (Table, View, and so on).

Select tables
Select tables for which you wish to create synonyms:
- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym
An Adapter for Transoft synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File nf29004.mas
FILE=DIVISION, SUFFIX=SQLTRN,$
SEGNAME=SEG1_4, SEGTYPE=S0,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF,$

Access File nf29004.acx
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=CON1,KEYS=1,WRITE=YES,$

Reference: Access File Keywords
This chart describes the keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the Transoft table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: ( \text{TABLENAME}=[\text{owner}.]\text{table} )</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is: ( \text{CONNECTION}=	ext{connection} ) CONNECTION=' ' indicates access to the local data source. Absence of the CONNECTION attribute indicates access to the default database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first ( n ) fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>KEYFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td>IXFLD</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- KEYFLD is the FIELDNAME of the common column from the parent table.</td>
</tr>
<tr>
<td></td>
<td>- IXFLD is the FIELDNAME of the common column from the related table.</td>
</tr>
<tr>
<td></td>
<td>KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.</td>
</tr>
</tbody>
</table>
**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Data Type Support**

Data types are specific to the underlying data source.
Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

```
ENGINE SQLTRN SET CONVERSION RESET
ENGINE SQLTRN SET CONVERSION format RESET
ENGINE SQLTRN SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLTRN SET CONVERSION format [PRECISION MAX]
```

where:

**SQLTRN**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**

Is any valid format supported by the data source. Possible values are:

- **INTEGER** which indicates that the command applies only to INTEGER columns.
- **DECIMAL** which indicates that the command applies only to DECIMAL columns.
- **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of **MAX**).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
Example: Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

ENGINE SQLTRN SET CONVERSION INTEGER PRECISION 7

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

ENGINE SQLTRN SET CONVERSION FLOAT PRECISION 14 3

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

ENGINE SQLTRN SET CONVERSION INTEGER RESET

The following example shows how to set the precision and scale attributes for all fields to the defaults:

ENGINE SQLTRN SET CONVERSION RESET

Customizing the Transoft Environment

In this section:
- Specifying a Timeout Limit
- Cancelling Long Requests
- Obtaining the Number of Rows Updated or Deleted

The Adapter for Transoft provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

How to:
Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to Transoft.

Syntax: How to Issue the TIMEOUT Command

ENGINE SQLTRN SET TIMEOUT \{nn|0\}
where:

**SQLTRN**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**nn**
Is the number of seconds before a time-out occurs. 30 is the default value.

**0**
Represents an infinite period to wait for a response.

## Cancelling Long Requests

### How to:
**Cancel Long Requests**

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

### Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose **Workspace, Configuration/Monitor, Java Services, DEFAULT**. Right-click on **DEFAULT** and select **Agents**.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select **Stop**.

## Obtaining the Number of Rows Updated or Deleted

### How to:
**Obtain the Number of Rows Updated or Deleted**

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking **Data Adapters** on the menu bar, clicking a configured adapter, and choosing **Change Settings** from the menu. The Change Settings pane opens.
**Syntax:**

How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLTRN SET PASSRECS {ON|OFF}
```

where:

**SQLTRN**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

**OFF**

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

### Optimization Settings

**In this section:**

- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

**How to:**
Optimize Requests

**Example:**
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

**Reference:**
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

```
SQL SQLTRN SET {OPTIMIZATION|SQLJOIN} setting
```

where:

- **SQLTRN**
  - Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

- **SQLJOIN**
  - Is a synonym for OPTIMIZATION.

- **setting**
  - Is the optimization setting. Valid values are as follows:

  - **ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

  - **OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:** SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :O00n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```sql
SQL SQLTRN SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
```

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```sql
SQL SQLTRN SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.'EMPINFO' T1, 'USER1'.'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID, T1.LN
ORDER BY T2.EID, T1.LN;
```

**Reference: SQL Generation in Optimization Examples**

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

**Optimizing Requests Containing IF-THEN-ELSE Virtual Fields**

**How to:**
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

**Example:**
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

**Reference:**
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
**Syntax:**

**How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields**

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLTRN SET OPTIFTHENELSE {ON | OFF}
```

where:

**SQLTRN**
- Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**
- Enables IF-THEN-ELSE optimization. This is the default.

**OFF**
- Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:**

**Using IF-THEN_ELSE Optimization Without Aggregation**

Consider the following request:

```sql
SQL SQLTRN SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN',T1.'FN',T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((((T1.'LN' = ' ') AND (T1.'FN' = ' ')
AND (T1.'DPT' = 'MIS')))));
```
Example: Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```
SQL SQLTRN SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
    ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
    WHERE (((T1.'LN' = 'SMITH')));
```

```
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
    WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```
SQL SQLTRN SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME IF DEF3 EQ 2
END
```

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
Reference: SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  \[ X = X + 1; \]
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

Note: Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX and MIN prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

Note: FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
The Adapter for Twitter® is a Candidate for Release.

Twitter is an online social networking and microblogging service that enables users to send and read text-based messages of up to 140 characters, called tweets. The Adapter for Twitter provides the ability to read tweets for a specific Screen Name and perform searches on a number of different parameters, including followers, status, and words indexed by Twitter in tweets.

Note: The Twitter API only returns the last 3,200 tweets for a particular Screen Name.

Topics:
- Configuring the Adapter for Twitter
- Creating Synonyms With the Adapter for Twitter
Configuring the Adapter for Twitter

In this section:
Declaring Connection Attributes

Configuring the adapter consists of specifying connection information and if necessary, authentication information for at least one connection.

Declaring Connection Attributes

How to:
Declare Connection Attributes

Reference:
Connection Attributes for the Adapter for Twitter

In order to access Twitter, the adapter requires connection information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one web services provider by including multiple SET CONNECTION_ATTRIBUTES commands.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   
   or
   
   From the Data Management Console, expand the Adapters folder.
   
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.
3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select **Configure**.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click **Configure**. The configured adapter is added to the Adapters list in the navigation pane.

**Reference:**  **Connection Attributes for the Adapter for Twitter**

The Adapter for Twitter is under the Social Media group folder.

**Connect parameters**

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.

**Twitter Url**

The URL of the Twitter API request. The default value is: https://api.twitter.com/1.1/

**Consumer Key**

A value which identifies your application to Twitter. Obtain this value from the settings page of your Twitter application at [https://dev.twitter.com/apps](https://dev.twitter.com/apps).

**Consumer Secret**

A value which identifies your application to Twitter. Used in conjunction with Consumer Key. Obtain this value from the settings page of your Twitter application.

**Access Token**

A value which identifies the user that your application is acting on behalf of. Obtain this value from the settings page of your Twitter application.

**Access Secret**

A value which identifies the user that your application is acting on behalf of. Used in conjunction with Access Token. Obtain this value from the settings page of your Twitter application.

**Select profile**

Is the profile where the connection will be stored. The default value is edaprof.
Creating Synonyms With the Adapter for Twitter

How to:
Create a Synonym

After adding a Twitter connection, a set of predefined synonyms and example procedures (FOCEXECs) can be created for this connection.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Adapters.
   The Adapters page opens.

2. Open the Twitter folder.

3. Right-click a connection and select Create Synonym from the drop-down menu.
The Select candidate(s) for Twitter Synonym(s) page opens, as shown in the following image.

4. Enter a folder name in the Application field or click the selector button (...) and navigate to one.

5. Click Create Synonyms and Samples.
Creating Synonyms With the Adapter for Twitter

The synonyms and sample procedures are created in the application folder, as shown in the following image.

![Image showing the application folder with subfolders and files]

**Note:**

- The metadata (Master Files and Access Files) is created in the parent folder.

- The Create Synonym process also loads a number of sample reports into the `twtsamp` subfolder that can be run out-of-the-box. These reports use sample text that is loaded during the Create Synonym process.
Using the Adapter for UniData

The Adapter for UniData allows applications to access UniData data sources. The adapter converts application requests into UniData calls and returns optimized answer sets to the requesting application.
Preparing the UniData Environment

How to: Set Up the Environment on Windows and UNIX

In order to use the Adapter for UniData, you must install the UniData driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Two additional steps are required to make UniData accessible to JDBC:

- All schema objects must be normalized by running CONVERT.SQL command in the native tool or via VSG(GUI-tool). This will make the SQLTables() call work properly.
- The old UniData 4.1 default schema must be migrated to current 6.0 and above schema-style using the MIGRATE.SQL command. This will make the SQLColumns() call work properly.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the UniData Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX or IBM i location for some JDBC Driver files to /usr/driver_files/mydriver.jar, issue the commands:

   ```
   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH
   ```

   Similarly, on Windows, you would issue the command:

   ```
   set CLASSPATH=c:\usr\driver_files\mydriver.jar;%CLASSPATH%
   ```

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace

   ```
   edastart -show
   ```

   and check the special services section displays "JSCOM3 active".
If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server's edaprint.log. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the Server Installation manual.

Configuring the Adapter for UniData

In this section:
- Declaring Connection Attributes
- Overriding the Default Connection
- Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

How to:
- Declare Connection Attributes
- Declare Connection Attributes Manually

Example:
- Declaring Connection Attributes

Reference:
- Connection Attributes for UniData

In order to connect to a UniData data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.
You can declare connections to more than one UniData data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

**Procedure: How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**.
   - or
   From the Data Management Console, expand the **Adapters** folder.
   The Adapters folder opens.
2. Expand the **Available** folder, if it is not already expanded.
3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select **Configure**.
   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.
6. Click **Configure**. The configured adapter is added to the Adapters list in the navigation pane.

**Reference: Connection Attributes for UniData**

The UniData adapter is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the **Configure** button.

**Connection name**

Logical name used to identify this particular set of connection attributes. The default is CON01.
**URL**

Location URL for the UniData data source.

**User**

Primary authorization ID by which you are known to the data source.

**Password**

Password associated with the primary authorization ID.

**Driver name**

Name for the UniData JDBC driver.

For example: com.ibm.u2.jdbc.UniJDBCDriver

See UniData documentation for the specific driver release you are using.

**Select profile**

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

---

**Syntax: How to Declare Connection Attributes Manually**

```sql
ENGINE SQLUND SET CONNECTION_ATTRIBUTES connection 'URL'/userid,password
```

where:

- **SQLUND**
  
  Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **connection**
  
  Is the connection name.

- **URL**
  
  Is the URL to the location of the UniData data source.

- **userid**
  
  Is the primary authorization ID by which you are known to the target database.
password

Is the password associated with the primary authorization ID.

**Example:** Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to a data source using the UniData Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

**Note:** Consult your vendor documentation for the exact name, port, and path.

ENGINE SQLUND SET CONNECTION_ATTRIBUTES CON1
'jdbc:unidata://rediron6:7000/MYUSER,PASSSQLUND

**Overriding the Default Connection**

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

If multiple connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

**Syntax:** How to Change the Default Connection

ENGINE SQLUND SET DEFAULT_CONNECTION connection

where:

SQLUND
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

FOC1671, Command out of sequence
**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  FOC1671, Command out of sequence.

**Example: Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```sql
ENGINE SQLUND SET DEFAULT_CONNECTION SAMPLENAME
```

**Controlling the Connection Scope**

**How to:**

Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

**Syntax:**

**How to Control the Connection Scope**

```sql
ENGINE SQLUND SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

- **SQLUND**
  - Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

- **FIN**
  - Disconnects automatically only after the session has been terminated. FIN is the default value.

- **COMMIT**
  - Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.
Managing UniData Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

How to:

Identify the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLUND to identify the Adapter for UniData.

Syntax: How to Identify the Adapter

FILE(NAME)=file, SUFFIX=SQLUND [,]$  

where:

file  
Is the file name for the Master File. The file name without the .mas extension can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLUND  
Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using UniData, you must locally install the RDBMS UniData Driver.
The Server can access third-party database tables across the UniData network. You must specify a URL for the data source and, possibly, a user ID and/or password for the database you are accessing. You can define these parameters in either the server global profile or in a user profile.

Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Sample Generated Synonym

**Reference:**
Synonym Creation Parameters for UniData
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

**Note:** If you are creating a synonym for a UniData data source, you must first add the syntax `SET SYNONYM=BASIC` to the edasprof.prf file.

**Procedure:** How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.
2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.
3. Click a connection for the configured adapter.
The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

Reference: Synonym Creation Parameters for UniData

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing External SQL Scripts from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

Owner/Schema. Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
Object name. Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify External SQL Scripts in the Restrict Object type to field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the Base Location field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the Document Name field, enter the file name with or without wild card characters.

- In the Document Extension field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the Base Location field, enter:

  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE

  The Document Extension is understood to be MBR. You can enter this value explicitly or leave the input box blank.

  During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

  DATASET=/ul/home2/apps/report3.sql

  When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the Cardinality check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.
With foreign key

Select the With foreign key check box to include within this synonym every table related to the current table by a foreign key. The resulting multi-table synonym describes all of the foreign key relationships of this table.

Dynamic columns

To specify that the Master File created for the synonym should not contain column information, select the Dynamic columns check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

For Subquery

Only available when External SQL Scripts is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see Data Type Support on page 2538.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.
**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Owner/Schema**

The user account that created the object or a collection of objects owned by a user.

**Type**

The object type (Table, View, and so on).

**Select tables**

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

**Example:** **Sample Generated Synonym**

An Adapter for UniData synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

**Master File nf29004.mas**

```
FILE=DIVISION, SUFFIX=SQLUND ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$
```

**Access File nf29004.acx**

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=CON1,KEYS=1,WRITE=YES,$
```

**Reference:** **Access File Keywords**

This chart describes keywords in the Access File.

<table>
<thead>
<tr>
<th><strong>Keyword</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGNAME</td>
<td>Value must be identical to the SEGNAME value in the Master File.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TABLENAME</td>
<td>Identifies the UniData table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows:</td>
</tr>
<tr>
<td></td>
<td>TABLENAME=[owner.]table</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>Indicates a previously declared connection. The syntax is:</td>
</tr>
<tr>
<td></td>
<td>CONNECTION=connection</td>
</tr>
<tr>
<td></td>
<td>CONNECTION=' ' indicates access to the local data source.</td>
</tr>
<tr>
<td></td>
<td>Absence of the CONNECTION attribute indicates access to the default database server.</td>
</tr>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first n fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>KEYFLD</td>
<td>Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair.</td>
</tr>
<tr>
<td>IXFLD</td>
<td>KEYFLD is the FIELDNAME of the common column from the parent table.</td>
</tr>
<tr>
<td></td>
<td>IXFLD is the FIELDNAME of the common column from the related table.</td>
</tr>
<tr>
<td></td>
<td>KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.</td>
</tr>
</tbody>
</table>
### Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns.</td>
</tr>
<tr>
<td></td>
<td>Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.</td>
</tr>
<tr>
<td></td>
<td>Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data Management</td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td>Impact Analysis</td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td>Copy</td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td>Cut</td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td>Properties</td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>

**Data Type Support**

Data types are specific to the underlying data source.
Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

```
ENGINE SQLUND SET CONVERSION RESET
ENGINE SQLUND SET CONVERSION format RESET
ENGINE SQLUND SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLUND SET CONVERSION format [PRECISION MAX]
```

where:

**SQLUND**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**

Is any valid format supported by the data source. Possible values are:

**INTEGER** which indicates that the command applies only to INTEGER columns.

**DECIMAL** which indicates that the command applies only to DECIMAL columns.

**REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```sql
ENGINE SQLUND SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```sql
ENGINE SQLUND SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```sql
ENGINE SQLUND SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```sql
ENGINE SQLUND SET CONVERSION RESET
```

---

**Customizing the UniData Environment**

**In this section:**

- Specifying a Timeout Limit
- Cancelling Long Requests
- Obtaining the Number of Rows Updated or Deleted

The Adapter for UniData provides several parameters for customizing the environment and optimizing performance.

**Specifying a Timeout Limit**

**How to:**

Issue the TIMEOUT Command

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to UniData.

**Syntax:** How to Issue the TIMEOUT Command

```sql
ENGINE SQLUND SET TIMEOUT {nn|0}
```
where:

**SQLUND**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**nn**
Is the number of seconds before a time-out occurs. 30 is the default value.

**0**
Represents an infinite period to wait for a response.

## Cancelling Long Requests

#### How to: Cancel Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

**Procedure: How to Cancel Long Requests**

1. From the Web Console menu bar choose **Workspace, Configuration/Monitor, Java Services, DEFAULT.** Right-click on **DEFAULT** and select **Agents.**

2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select **Stop.**

## Obtaining the Number of Rows Updated or Deleted

#### How to: Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking **Data Adapters** on the menu bar, clicking a configured adapter, and choosing **Change Settings** from the menu. The Change Settings pane opens.
**Syntax:** How to Obtain the Number of Rows Updated or Deleted

ENGINE SQLUND SET PASSRECS {ON|OFF}

**where:**

**SQLUND**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

**OFF**

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

**Optimization Settings**

*In this section:*

- Optimizing Requests
- Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

How to:
Optimize Requests

Example:
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

Reference:
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

SQL SQLUND SET {OPTIMIZATION|SQLJOIN} setting

where:

SQLUND
Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

SQLJOIN
Is a synonym for OPTIMIZATION.

setting
Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:**  **SQL Requests Passed to the RDBMS With Optimization OFF**

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLUND SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
```

```
SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
FROM 'USER1'.EMPINFO T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
```

```
SELECT T2.EID FROM 'USER1'.FUNDTRAN T2 WHERE (T2.EID = ?) FOR FETCH ONLY;
```

**Example:**  **SQL Requests Passed to the RDBMS With Optimization ON**

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLUND SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

AGGREGATION DONE ...
SELECT T2.EID,T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID,T1.LN
ORDER BY T2.EID,T1.LN;

Reference: SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

How to:
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

Example:
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

Reference:
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
Syntax: How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLUND SET OPTIFTHENELSE {ON | OFF}
```

where:

- **SQLUND**
  - Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

- **ON**
  - Enables IF-THEN-ELSE optimization. This is the default.

- **OFF**
  - Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

Example: Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
SQL SQLUND SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = ' ') AND (T1.'FN' = ' '))
AND (T1.'DPT' = 'MIS')));
```
**Example: Using IF-THEN_ELSE Optimization With Aggregation**

Consider the following request:

```sql
SQL SQLUND SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
    WHERE (((T1.'LN' = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
    WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

**Example: Using IF-THEN_ELSE Optimization With a Condition That Is Always False**

```sql
SQL SQLUND SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END
```

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
Reference: SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  
  \[ X = X + 1; \]
- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

  Note: Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX. and MIN. prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

  Note: FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Optimization Settings
Using the Adapter for UniVerse

The Adapter for UniVerse allows applications to access UniVerse data sources. The adapter converts data or application requests into native UniVerse statements and returns optimized answer sets to the requesting program.

Topics:
- Preparing the UniVerse Environment
- Configuring the Adapter for UniVerse
- Managing UniVerse Metadata
- Customizing the UniVerse Environment
- Optimization Settings
Preparing the UniVerse Environment

For the Adapter for UniVerse, no environment variables need to be set prior to starting the server. However the UniVerse ODBC, UniCall Interface (UCI), and UniRPC need to be installed and configured according to the RocketSoftware UniVerse ODBC Guide. The UniRPC daemon should be running on both client and server machines.

**Note:** The adapter is relational and can only access tables and views, not UV files. The UV files can be converted to tables or views as described in UV SQL Administration for DBAs.

Configuring the Adapter for UniVerse

**In this section:**
- Declaring Connection Attributes
- Overriding the Default Connection
- Controlling the Connection Scope

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.
Declaring Connection Attributes

**How to:**
- Declare Connection Attributes
- Declare Connection Attributes Manually

**Example:**
- Declaring Connection Attributes

**Reference:**
- Connection Attributes for UniVerse
- Updating the Connection String

In order to connect to an UniVerse database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one UniVerse database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to UniVerse Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

**Procedure:** **How to Declare Connection Attributes**

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
From the Data Management Console, expand the Adapters folder.
The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for UniVerse

The UniVerse adapter is under the SQL group folder.
The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Connection name
Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource
The data source name (DSN). There is no default data source name. You must enter a value.

User
User name by which you are known to UniVerse. It is ignored when connecting to a local UniVerse server.

Password
Password associated with the user name. It is ignored when connecting to a local UniVerse server.

Schema
UniVerse schema name including the entire path to it enclosed in single quotation marks.
Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

ENGINE SQLUV SET CONNECTION_ATTRIBUTES connection
DSN_name/userid,password [;dbname]

where:

SQLUV

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

collection

Is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between connection and DSN_name.

DSN_name

Is the UniVerse Data Source Name (DSN) you wish to access. It must match an entry in the uci.config or uvodbc.config file, depending on the UniVerse release. Please consult the corresponding version of the RocketSoftware UniVerse ODBC Guide.

userid

Is the primary authorization ID by which you are known to UniVerse.

password

Is the password associated with the primary authorization ID.

dbname

Also referred to as schema, is the name of the UniVerse database used for this connection. The database name, including path, must be inclosed in single quotation marks.
Declaring Connection Attributes

Example: The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the UniVerse DSN named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

ENGINE SQLUV SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS

Updating the Connection String

Reference: The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Web Console Migrate option migrates your server settings to the newer release. To access this option, select Workspace, then Configuration/Monitor from the menu bar. Right-click Migrate from the Server folder in the navigation pane, and select Configure. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the Migrate button. This is the recommended approach.

If you choose not to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=value.

For example, suppose that prior to Version 7 Release 6.1, the connection was defined as:

ENGINE SQLUV SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd

When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

CONNECTION=DSN_A

If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

ENGINE SQLUV SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
Overriding the Default Connection

**How to:**
Change the Default Connection

**Example:**
Selecting the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

**Syntax:**  **How to Change the Default Connection**

```sql
ENGINE SQLUV SET DEFAULT_CONNECTION connection
```

where:

**SQLUV**
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**connection**
Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```FOC1671, Command out of sequence```

**Note:**

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command serves as the default connection.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```FOC1671, Command out of sequence```

**Example:**  **Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLENAME as the default database server:

```sql
ENGINE SQLUV SET DEFAULT_CONNECTION SAMPLENAME
```
Controlling the Connection Scope

How to:
Control the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

ENGINE SQLUV SET AUTODISCONNECT ON {FIN | COMMAND | COMMIT}

where:

SQLUV
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN
Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMAND
Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

COMMIT
Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing UniVerse Metadata

In this section:

Creating Synonyms
UniVerse Data Type Support
Changing the Precision and Scale of Numeric Columns

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the data source's structure and the server mapping of the UniVerse data types.
Creating Synonyms

**How to:**
Create a Synonym

**Example:**
Sample Generated Synonym

**Reference:**
Synonym Creation Parameters for UniVerse
Access File Keywords
Managing Synonyms

Synonyms define unique names (or aliases) for each UniVerse table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   
The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   
The *Select adapter to configure* or *Select connection to create synonym* pane opens.

3. Click a connection for the configured adapter.
   
The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.
   
The Status pane indicates that the synonym was created successfully.
The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2821.

**Reference:**  Synonym Creation Parameters for UniVerse

The following list describes the synonym creation parameters for which you can supply values.

**Restrict Object Type to**

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

**Filter by Owner/Schema and Object name**

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.
**Location of External SQL Scripts**

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MLIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

**Cardinality**

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

**Dynamic columns**

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.
**For Subquery**

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string is not parameterized (that is, does not contain parameter markers, such as ? or :), it will be processed as a subquery embedded into a FROM clause of the generated SELECT query. Otherwise, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Customize data type mappings**

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *UniVerse Data Type Support* on page 2566.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**Owner/Schema**

The user account that created the object or a collection of objects owned by a user.

**Type**

The object type (Table, View, and so on).
Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, click the Select All button.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for UniVerse synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

FILE=DIVISION, SUFFIX=SQLUV ,$
SENAME=SEGL_4, SEGTYPE=S0 ,$
FIELD=DIVISION4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9, I4, MISSING=ON ,$

Generated Access File nf29004.acx

SENAME=NF29004 ,
TABLENAME=NF29004,
CONNECTION=CONN_UV,
KEYS=0
,$

Reference: Access File Keywords

This chart describes keywords in the Access File.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SENAME</td>
<td>Value must be identical to the SENAME value in the Master File.</td>
</tr>
</tbody>
</table>
| TABLENAME  | Name of the table or view. This value can include a location or owner name as follows: 
TABLENAME=[location.][owner.]tablename |
| CONNECTION | Indicates a previously declared connection. The syntax is: 
CONNECTION=connection 
CONNECTION='' indicates access to the local UniVerse database server. Absence of the CONNECTION attribute indicates access to the default database server. |
<table>
<thead>
<tr>
<th><strong>Keyword</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>KEYS</td>
<td>Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first ( n ) fields in the Master File segment.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Specifies whether write operations are allowed against the table.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).</td>
</tr>
<tr>
<td>INDEX_UNIQUE</td>
<td></td>
</tr>
<tr>
<td>INDEX_COLUMNS</td>
<td></td>
</tr>
<tr>
<td>INDEX_ORDER</td>
<td></td>
</tr>
</tbody>
</table>

**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th><strong>Option</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. **Note:** To update the synonym, it is strongly recommended that you use the graphical interface provided by the <em>Open</em> option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. **Note:** This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
<tr>
<td>Data Profiling</td>
<td>Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.</td>
</tr>
<tr>
<td><strong>Option</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Refresh Synonym (if applicable)</td>
<td>Regenerates the synonym. Use this option if the underlying object has been altered.</td>
</tr>
<tr>
<td><strong>Data Management</strong></td>
<td>Followed by these options, if applicable:</td>
</tr>
<tr>
<td></td>
<td><strong>Recreate DBMS Table.</strong> Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)</td>
</tr>
<tr>
<td></td>
<td><strong>Delete All Data.</strong> Deletes all existing data. You are asked to confirm this selection before the data is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert Sample Data.</strong> Inserts specified number of sample records, populating all fields with counter values.</td>
</tr>
<tr>
<td></td>
<td><strong>Reorganize.</strong> Recreates the data source table preserving original data.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is not available in the Web Console.</td>
</tr>
<tr>
<td><strong>Impact Analysis</strong></td>
<td>Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.</td>
</tr>
<tr>
<td><strong>Copy</strong></td>
<td>Copies the synonym to the clipboard.</td>
</tr>
<tr>
<td><strong>Delete</strong></td>
<td>Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.</td>
</tr>
<tr>
<td><strong>Cut</strong></td>
<td>Deletes the synonym and places it on the clipboard.</td>
</tr>
<tr>
<td><strong>Properties</strong></td>
<td>Displays the properties of the synonym, including physical location, last modified date, description, and privileges.</td>
</tr>
</tbody>
</table>
UniVerse Data Type Support

The following tables describe how the server maps UniVerse data types.

<table>
<thead>
<tr>
<th>UniVerse Data Type</th>
<th>Server Data Type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>USAGE</td>
<td>ACTUAL</td>
</tr>
<tr>
<td><strong>Date-Time Data Types</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DATE</td>
<td>HYYMDS</td>
<td>HYYMDS</td>
</tr>
<tr>
<td>TIME</td>
<td>A8</td>
<td>A8</td>
</tr>
<tr>
<td><strong>Numeric Data Types</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SMALLINT</td>
<td>I4</td>
<td>I6</td>
</tr>
<tr>
<td>INTEGER</td>
<td>I11</td>
<td>I4</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>P11</td>
<td>P8</td>
</tr>
<tr>
<td>DECIMAL(p,s)</td>
<td>Pp,s</td>
<td>P1,....,16</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td>FLOAT(p)</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td>REAL</td>
<td>D20.2</td>
<td>D8</td>
</tr>
<tr>
<td><strong>Other Data Types</strong></td>

<tr>
<td>BIT (n)</td>
<td>Not supported.</td>
<td>Not supported.</td>
</tr>
<tr>
<td>VARBIT</td>
<td>Not supported.</td>
<td>Not supported.</td>
</tr>
</tbody>
</table>

The following table lists how the server maps Character data types. This mapping can be changed based on the value of LONGCHAR. The default value is ALPHA.
<table>
<thead>
<tr>
<th>UniVerse Data Type</th>
<th>Remarks</th>
<th>LONGCHAR ALPHA</th>
<th>LONGCHAR TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR ( (n) )</td>
<td>( n ) is an integer between 1 and 254.</td>
<td>( A_n )</td>
<td>( A_n )</td>
</tr>
<tr>
<td>VARCHAR ( (m) )</td>
<td>( n ) is an integer between 1 and 256.</td>
<td>( A_n V )</td>
<td>( A_n V )</td>
</tr>
<tr>
<td></td>
<td>( n ) is an integer between 257 and 32767.</td>
<td>( A_n V )</td>
<td>( TX50 )</td>
</tr>
<tr>
<td></td>
<td>( m ) is an integer between 1 and 65535. If ( m ) is greater than 32767, map the field as TX, otherwise data beyond 32767 will be truncated.</td>
<td>TX</td>
<td>TX</td>
</tr>
<tr>
<td>NCHAR ( (n) )</td>
<td>( n ) is an integer between 1 and 254.</td>
<td>( A_n )</td>
<td>( A_n )</td>
</tr>
<tr>
<td>NVARCHAR ( (m) )</td>
<td>( n ) is an integer between 1 and 256.</td>
<td>( A_n V )</td>
<td>( A_n V )</td>
</tr>
<tr>
<td></td>
<td>( n ) is an integer between 257 and 32767.</td>
<td>( A_n V )</td>
<td>( TX50 )</td>
</tr>
<tr>
<td></td>
<td>( m ) is an integer between 1 and 65535. If ( m ) is greater than 32767, map the field as TX, otherwise data beyond 32767 will be truncated.</td>
<td>TX</td>
<td>TX</td>
</tr>
</tbody>
</table>

**Note:** The main purpose of the LONGCHAR setting is to provide compatibility with previous releases of the server. This SET parameter was designed to control processing of DBMS Character data types and was never intended for DBMS LOB.
### Changing the Precision and Scale of Numeric Columns

**How to:**

Override the Default Precision and Scale

**Example:**

Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax:**

**How to Override the Default Precision and Scale**

```sql
ENGINE SQLUV SET CONVERSION RESET
ENGINE SQLUV SET CONVERSION format RESET
ENGINE SQLUV SET CONVERSION format [PRECISION precision [scale]]
ENGINE SQLUV SET CONVERSION format [PRECISION MAX]
```

**where:**

**SQLUV**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**

Is any valid format supported by the data source. Possible values are:

- **INTEGER** which indicates that the command applies only to INTEGER columns.
- **DECIMAL** which indicates that the command applies only to DECIMAL columns.
- **REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
**FLOAT** which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
**Example:** Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```sql
ENGINE SQLUV SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```sql
ENGINE SQLUV SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```sql
ENGINE SQLUV SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```sql
ENGINE SQLUV SET CONVERSION RESET
```

**Customizing the UniVerse Environment**

**In this section:**

- Displaying Multivalued Columns in UniVerse
- Obtaining the Number of Rows Updated or Deleted
- Controlling Transactions

The Adapter for UniVerse provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.

**Displaying Multivalued Columns in UniVerse**

**How to:**

Set OPENMODE NNF

The OPENMODE NNF setting determines how tables with multivalued columns are treated. For the Adapter for Universe to function properly, OPENMODE must be set to NNF in edasprof.prf.

**Syntax:**

How to Set OPENMODE NNF

```sql
ENGINE SQLUV SET OPENMODE NNF
```
where:

**SQLUV**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**OPENMODE NNF**

Allows the user application to see UniVerse tables the way they actually exist, including any multi-valued columns.

### Obtaining the Number of Rows Updated or Deleted

**How to:**

Obtain the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

**Tip:** You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.

**Syntax:**

**How to Obtain the Number of Rows Updated or Deleted**

ENGINE SQLUV SET PASSRECS {ON|OFF}

where:

**SQLUV**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**ON**

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

**OFF**

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.
Controlling Transactions

How to: Issue the TRANSACTIONS Command

In order to perform Data Definition Language commands in UniVerse using the server, the TRANSACTION setting must be set to OFF.

Syntax: How to Issue the TRANSACTIONS Command

ENGINE SQLUV SET TRANSACTIONS {ON | OFF}

where:

SQLUV
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON
Turns transaction processing on. ON is the default value.

OFF
Turns transaction processing off.

Optimization Settings

In this section:

Optimizing Requests
Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.
Optimizing Requests

**How to:**
Optimize Requests

**Example:**
SQL Requests Passed to the RDBMS With Optimization OFF
SQL Requests Passed to the RDBMS With Optimization ON

**Reference:**
SQL Generation in Optimization Examples

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

**Syntax:**

```sql
SQL SQLUV SET {OPTIMIZATION|SQLJOIN} setting
```

*where:*

- **SQLUV**
  Is the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.

- **SQLJOIN**
  Is a synonym for OPTIMIZATION.

- **setting**
  Is the optimization setting. Valid values are as follows:

  - **ON** instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

  - **OFF** instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.
Both OPTIMIZATION settings produce the same report.

**Example:** SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000n, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL SQLUV SET OPTIMIZATION OFF
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END

In a trace operation, you will see the following output:

(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
  SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
  FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
  SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
  FOR FETCH ONLY;
```

**Example:** SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL SQLUV SET OPTIMIZATION ON
JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
END
```
In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
SELECT T2.EID, T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
FROM 'USER1'.EMPINFO T1, 'USER1'.FUNDTRAN T2
WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
GROUP BY T2.EID, T1.LN
ORDER BY T2.EID, T1.LN;
```

Reference: SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

Optimizing Requests Containing IF-THEN-ELSE Virtual Fields

How to:
Optimize Requests Containing IF-THEN-ELSE Virtual Fields

Example:
Using IF-THEN_ELSE Optimization Without Aggregation
Using IF-THEN_ELSE Optimization With Aggregation
Using IF-THEN_ELSE Optimization With a Condition That Is Always False

Reference:
SQL Limitations on Optimization of DEFINE Expressions

The adapter can optimize DML requests to the server that include virtual (DEFINE) fields created using IF-THEN-ELSE syntax. In certain cases, such DEFINE fields can be passed to the RDBMS as expressions, enhancing performance and minimizing the size of the answer set returned to the server.

Tip: You can change this setting manually or from the Web Console by clicking Data Adapters on the menu bar, clicking a configured adapter, and choosing Change Settings from the menu. The Change Settings pane opens.
**Syntax:** How to Optimize Requests Containing IF-THEN-ELSE Virtual Fields

When you issue the SET OPTIFTHENELSE command, the adapter attempts to deliver the construct of a DML IF-THEN-ELSE DEFINE field to the RDBMS as an expression. The DEFINE field must be an object of a selection test or an aggregation request. The DEFINE definition may be specified in the DML request or in the Master File.

```sql
SQL SQLUV SET OPTIFTHENELSE {ON | OFF}
```

Where:

- **SQLUV**
  - Indicates the target RDBMS. You can omit this value if you previously issued the SET SQLENGINE command.
- **ON**
  - Enables IF-THEN-ELSE optimization. This is the default.
- **OFF**
  - Disables IF-THEN-ELSE optimization.

There is no guarantee that the SQL that is generated will improve performance for all requests. If you find that this feature does not improve performance, set OPTIFTHENELSE OFF to disable the feature.

IF-THEN-ELSE optimization applies to SELECT statements created as a result of requests and is subject to SQL limitations on optimization of DEFINE expressions.

**Example:** Using IF-THEN_ELSE Optimization Without Aggregation

Consider the following request:

```sql
SQL SQLUV SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF1 = IF (LAST_NAME EQ ' ') AND (FIRST_NAME EQ ' ') AND (DEPARTMENT EQ 'MIS') THEN 1 ELSE 0;
END
TABLE FILE EMPINFO
PRINT DEPARTMENT LAST_NAME FIRST_NAME
WHERE DEF1 EQ 1
END
```

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF1 EQ 1 test:

```sql
SELECT T1.'LN', T1.'FN', T1.'DPT' FROM USER1.'EMPINFO' T1
WHERE ((((((T1.'LN' = '') AND (T1.'FN' = '')) AND (T1.'DPT' = 'MIS')))));
```
**Example:** Using IF-THEN_ELSE Optimization With Aggregation

Consider the following request:

```sql
SQL SQLUV SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF2 = IF LAST_NAME EQ 'SMITH' THEN 1 ELSE IF LAST_NAME EQ 'JONES' THEN 2
ELSE IF LAST_NAME EQ 'CARTER' THEN 3 ELSE 0;
END

TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 1
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 1 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
WHERE (((T1.'LN' = 'SMITH')));
```

```sql
TABLE FILE EMPINFO
SUM MAX.LAST_NAME IF DEF2 EQ 2
END

The adapter generates an SQL request that incorporates the IF-THEN-ELSE condition corresponding to the WHERE DEF2 EQ 2 test:

```sql
SELECT MAX(T1.'LN') FROM USER1.'EMPINFO' T1
WHERE (((NOT (T1.'LN' = 'SMITH')) AND (T1.'LN' = 'JONES')));
```

**Example:** Using IF-THEN_ELSE Optimization With a Condition That Is Always False

```sql
SQL SQLUV SET OPTIFTHENELSE ON
DEFINE FILE EMPINFO
DEF3 = IF FIRST_NAME EQ 'RITA' THEN 1 ELSE 0;
END

TABLE FILE EMPINFO
PRINT FIRST_NAME
IF DEF3 EQ 2
END

Because DEF3 EQ 2 will never be true, the adapter passes the WHERE test 1=0 (which is always false) to the RDBMS, returning zero records from the RDBMS:

```sql
SELECT T1.'FN' FROM USER1.'EMPINFO' T1 WHERE (1 = 0);
```
Reference: SQL Limitations on Optimization of DEFINE Expressions

Since the FOCUS reporting language is more extensive than native SQL, the data adapter cannot pass certain DEFINE expressions to the RDBMS for processing. The data adapter does not offload DEFINE-based aggregation and record selection if the DEFINE includes:

- User-written subroutines.
- Self-referential expressions, such as:
  
  \[ X = X + 1; \]

- EDIT functions for numeric-to-alpha or alpha-to-numeric field conversions.
- DECODE functions for field value conversions.
- Relational operators INCLUDES and EXCLUDES.
- FOCUS subroutines ABS, INT, MAX, MIN, LOG, and SQRT.

Note: Do not confuse the FOCUS user-written subroutines MAX and MIN with the MAX and MIN prefix operators. DEFINE fields cannot include prefix operators.

- Expressions involving fields with ACTUAL=DATE, except for the subtraction of one DATE field from another and all logical expressions on DATE fields.
- Date-time manipulation handled by the FOCUS date-time functions is not converted to SQL.
- Financial Modeling Language (FML) cell calculations. FML is also referred to as Extended Matrix Reporting (EMR).

Note: FML report requests are extended TABLE requests. The Financial Modeling Language provides special functions for detailed reporting. Consult your FOCUS documentation for more information.

In addition, IF-THEN-ELSE optimization does not support the following features:

- Any type of DECODE expression.
- STATIC SQL.
- IF/WHERE DDNAME.
- Partial date selection.
Using the Adapter for VSAM

The Adapter for VSAM allows applications to access VSAM data sources. The adapter converts application requests into native VSAM statements and returns optimized answer sets to the requesting application or it inserts the data from an application to the data source. VSAM ESDS, KSDS, and RRDS data sources are supported in Read/Write mode.

The Adapter for VSAM can access VSAM files in batch mode (where VSAM clusters are allocated to the server).

You can also access compressed datasets with this adapter. However, the actual compression is done using the ZCOMP Exit. For details, see Data Set Compression Exit: ZCOMP on page 2795.

Topics:
- Preparing the Environment for VSAM
- Configuring the Adapter for VSAM
- Managing VSAM Metadata
- Associating a VSAM Data Source With a Master File
- Standard Master File Attributes for a VSAM Data Source
- Redefining a Field in a VSAM Data Source
- Extra-Large Record Length Support
- Describing Multiple Record Types
- Combining Multiply-Occurring Fields and Multiple Record Types
- Establishing VSAM Data and Index Buffers
- Using a VSAM Alternate Index
- VSAM Record Selection Efficiencies
- Maintaining VSAM KSDS Data Sources
- Using VSAM Relative Record Data Set (RRDS) Files
- Reviewing SQL Updates to VSAM Data Sources
Preparing the Environment for VSAM

The Adapter for VSAM does not require setting any environment variables.
You can configure the Adapter for VSAM from the Web Console without completing any preparation steps.

Configuring the Adapter for VSAM

How to:
Configure the Adapter for VSAM

You can configure the adapters from the Web Console or the Data Management Console.

Procedure: How to Configure the Adapter for VSAM
You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   or
   From the Data Management Console, expand the Adapters folder.
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Note: The VSAM adapter is under the Sequential and Indexed group folder. No input parameters are required.
Managing VSAM Metadata

In this section:
Creating Synonyms

When the server accesses a data source, it interprets the data stored there based on instructions in a synonym that you create, which describes the structure of the data source and the server mapping of the VSAM data types.

Creating Synonyms

How to:
Create a Synonym

Reference:
Synonym Creation Parameters for VSAM
Managing Synonyms

Synonyms define unique names (or aliases) for each VSAM file or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File that represents the server metadata.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Applications.
   The Applications page opens.
2. Click the New button and select Synonym from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.
3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.
4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click Create Synonym.

The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

Reference: Synonym Creation Parameters for VSAM

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

Select File System Option

Under File System Selection, choose one of the following options:

- **Fully qualified PDS name** to indicate a partitioned dataset on MVS.
  
  In the input boxes provided, enter a PDS name preceded by a double slash (//) and a Member name containing the location of the COBOL FD source. If you wish, you can filter the member name using a wildcard character (%).

  or

- **Absolute HFS directory pathname** to indicate a hierarchical file structure on USS.
  
  In the input boxes provided, type a Directory name to specify the HFS location that contains the COBOL FD and File name and File extension. If you wish, you can filter the file and extension using a wildcard character (%).

Click Submit

The Create Synonym pane (Step 2 of 2) opens.

If selected, the filtered COBOL definition is displayed at the top of the pane.
Enter the following parameters, as required:

**Validate**

Select the Validate check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See Validation for Special Characters and Reserved Words on page 2821 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: ' -' ; ' ' ; ' ' \; '/'; ','; '$'. No checking is performed for names.

**Make unique**

Select the Make unique check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

**Set COBOL FD translation options**

Optionally, select Customize COBOL FD conversion options to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see Customization Options for COBOL File Descriptions on page 2775.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Extended data format attributes**

This option provides data portability between servers by enabling processing of data loaded in different encoding systems.

Click the Extended data format attributes check box to display the Codepage option.

In the input box provided, enter the code page of the stored data. Your entry is added to the Master File of the generated synonym.
Note: The code page you specify here must one for which you have requested a customized code page conversion table as part of your NLS configuration. If you have not already requested a conversion table for the designated code page, you can do so now. On the Web Console menu bar, click Workspace, then Configuration, and choose NLS under General settings. The NLS Configuration Wizard opens. Click Customize code page conversion tables and select the check box for the code page you wish to use. Click the Save and Restart button to implement your new setting.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the Overwrite existing synonyms check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Create Synonym parameters

Default Synonym Name

This column displays the names that will be assigned to each synonym. To assign different names, replace the respective displayed values. You have these additional options:

- To select all synonyms in the list, select the check box to the left of the Default Synonym Name column heading.
- Enter a cluster name under Dataset Location to associate it with a particular metadata description. The cluster name is embedded in the Master File. If you do not enter the cluster name during the synonym creation process, you will have to add it dynamically at run time.
- To select specific synonyms, select the corresponding check boxes.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
</tbody>
</table>
| Data Profiling                     | Data Profiling provides the data characteristics for synonym columns.  
Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.  
Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls. |
| Refresh Synonym (if applicable)    | Regenerates the synonym. Use this option if the underlying object has been altered.                                                          |
| Data Management                    | Followed by these options, if applicable:  
**Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated.  
(Note that the table will be dropped and recreated. During the process, data may be lost.)  
**Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted.  
**Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values.  
**Reorganize.** Recreates the data source table preserving original data.  
**Note:** This option is not available in the Web Console. |
### Option | Description
---|---
**Impact Analysis** | Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS* manual for details about Impact Analysis reports.

**Copy** | Copies the synonym to the clipboard.

**Delete** | Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.

**Cut** | Deletes the synonym and places it on the clipboard.

**Properties** | Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

---

### Associating a VSAM Data Source With a Master File

#### How to:
- Specify a Physical File Location for the VSAM Data Source
- Specify the Location of VSAM Files Manually

#### Example:
- Allocating a VSAM Data Source Using the DATASET Attribute
- Overriding DATASET With a FILEDEF Command
- Defining Path Clusters in JCL

You can associate a VSAM file with a Master File using the following methods:

- **DATASET attribute in a Master File.** The DATASET attribute in a Master File specifies the physical location for the data source to be allocated. This attribute is used at the file declaration level of the Master File. The CREATE SYNONYM facility uses the DATASET attribute in the Master File.

- **FILEDEF command.** An explicit allocation (FILEDEF) of data for the Master File is checked for when a DATASET attribute is detected. If an explicit allocation is found, the DATASET attribute is ignored and the allocation is used.
If the data file name is not allocated, an internal command is issued to perform the allocation using the DATASET value. This allocation is stored temporarily and is released when a new Master File is used or when the session terminates.

**Syntax:**

**How to Specify a Physical File Location for the VSAM Data Source**

The DATASET attribute is used at the file declaration level of the Master File. The syntax is

{DATASET|DATA}='filename'

where:

filename

Is the platform-dependent physical name of the data source.

**Note:** If a DATASET allocation is in effect, a CHECK FILE command must be issued in order to override it by an explicit allocation command. The CHECK FILE command will deallocate the allocation created by DATASET.

**Example:**

**Allocating a VSAM Data Source Using the DATASET Attribute**

The following example illustrates how to allocate a VSAM data source on the file declaration level and for an alternate index:

FILE=EXERVSM1, SUFFIX=VSAM, DATASET='VSAM1.CLUSTER1',$
SEGNAME=ROOT , SEGTYPE=S0,$
GROUP=KEY1 , ALIAS=KEY , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD1 , ALIAS=F1 , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD2 , ALIAS=F2 , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD3 , ALIAS=DD1 , FORMAT=A4, ACTUAL=A4 , FIELDTYPE = I ,
DATASET='VSAM1.INDEX1' ,$
FIELD=FLD4 , ALIAS=F4 , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD5 , ALIAS=F5 , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD6 , ALIAS=F6 , FORMAT=A4, ACTUAL=A4 ,$
FIELD=FLD7 , ALIAS=F7 , FORMAT=A4, ACTUAL=A4 ,

**Example:**

**Overriding DATASET With a FILEDEF Command**

You can override the DATASET value in the Master File with a FILEDEF command. The FILEDEF can be done locally within a procedure (before accessing the file) or within the profile. For example,

FILEDEF vsamfile DISK filename

where:

vsamfile

Is the logical metadata reference name matching the physical file name.
filename

Is the OpenVMS file name. It may be any valid OpenVMS file specification or logical name pointing to a file.

Syntax: How to Specify the Location of VSAM Files Manually

VSAM data sets may be allocated with JCL

//QAVSM DD DISP=SHR, DSN=cluster_name

or with DYNAM

DYNAM ALLOC FILE QAVSM DA cluster_name SHR REUSE

or in a Master File as

DATASET='dataset_name,'$

where:

cluster_name

Is the name of the VSAM cluster.

dataset_name

Is the name of the data set on MVS.

Note that if you are using an alternate index (an additional, separate index structure that enables you to access records in a VSAM data source based on a key other than the primary key for that data source), the alternate index must be associated with the base cluster it describes by a path that is stored in a separate data source, see Using VSAM Relative Record Data Set (RRDS) Files on page 2640. In addition to defining the location of the base cluster, you must define the path clusters either in IRUNJCL or using a DYNAM command. For details about logical processing with alternate indexes, see Reporting From Files With Alternate Indexes on page 2629.

Note: The Adapter for VSAM supports full read/write access.

Example: Defining Path Clusters in JCL

//VSAMFL1 DD DISP=OLD, DSN=EDABXV.VSAM.AXINDEX1.PATH
//VSAMFL2 DD DISP=OLD, DSN=EDABXV.VSAM.AXINDEX2.PATH
Standard Master File Attributes for a VSAM Data Source

In this section:
- Describing a Group Field
- Using the OCCURS Attribute
- Describing a Parallel Set of Repeating Fields
- Describing a Nested Set of Repeating Fields
- Using the POSITION Attribute
- Specifying the ORDER Field

Most standard Master File attributes are used with VSAM data sources in the standard way.

- **SUFFIX.** The SUFFIX attribute in the file declaration for these data sources has the value VSAM.

- **SEGNAME.** The SEGNAME attribute of the first or root segment in a Master File for a VSAM data source must be ROOT. The remaining segments can have any valid segment name.

  The only exception involves unrelated RECtypes, where the root SEGNAME must be DUMMY.

  All non-repeating data goes in the root segment. The remaining segments may have any valid name from 1 to 8 characters.

  Any segment except the root is the descendant, or child, of another segment. The PARENT attribute supplies the name of the segment that is the hierarchical parent or owner of the current segment. If no PARENT attribute appears, the default is the immediately preceding segment. The PARENT name may be one to eight characters.

- **SEGTYPE.** The SEGTYPE attribute should be S0 for VSAM data sources.

- **GROUP.** The keys of a VSAM data source are defined in the segment declarations as GROUPs consisting of one or more fields.
Describing a Group Field

**How to:**
Describe a VSAM Group Field

**Example:**
Describing a VSAM Group Field
Describing a VSAM Group Field With Multiple Formats
Accessing a Group Field With Multiple Formats

A single-segment data source may have only one key field, but it must still be described with a GROUP declaration. The group must have ALIAS=KEY.

Groups can also be assigned simply to provide convenient reference names for groups of fields. Suppose that you have a series of three fields for an employee: last name; first name; and middle initial. You use these three fields consistently to identify the employee. You can identify the three fields in your Master File as a GROUP named EMPINFO. Then, you can refer to these three linked fields as a single unit, called EMPINFO. When using the GROUP feature for non-keys, the parameter ALIAS= must still be used, but should not equal KEY.

For group fields, you must supply both the USAGE and ACTUAL formats in alphanumeric format. The length must be exactly the sum of the subordinate field lengths.

The GROUP declaration USAGE attribute specifies how many positions to use to describe the key in a VSAM KSDS data source. If a Master File does not completely describe the full key at least once, the following warning message appears:

(FOC1016) INVALID KEY DESCRIPTION IN MASTER FILE

The cluster key definition is compared to the Master File for length and displacement.

When you expand on the key in a RECTYPE data source, describe the key length in full on the last non-OCCURS segment on each data path.

Do not describe a group with ALIAS=KEY for OCCURS segments.

If the fields that make up a group key are not alphanumeric fields, the format of the group key is still alphanumeric, but its length is determined differently. The ACTUAL length is still the sum of the subordinate field lengths. The USAGE format, however, is the sum of the internal storage lengths of the subordinate fields. You determine these internal storage lengths as follows:

- Fields of type I have a value of 4.
- Fields of type F have a value of 4.
Fields of type P that are 8 bytes can have a USAGE of P15 or P16 (sign and decimal for a total of 15 digits). Fields that are 16 bytes have a USAGE of P17 or larger.

Fields of type D have a value of 8.

Alphanumeric fields have a value equal to the number of characters they contain as their field length.

**Note:**

Since all group fields must be defined in alphanumeric format, those that include numeric component fields should not be used as verb objects in a report request.

The MISSING attribute is not supported on the group field, but is supported on the individual fields comprising the group.

**Syntax:**

**How to Describe a VSAM Group Field**

GROUP = *keyname*, ALIAS = KEY, USAGE = Ann, ACTUAL = Ann ,$

where:

*keyname*

Can have up to 66 characters.

**Example:**

**Describing a VSAM Group Field**

In the library data source, the first field, PUBNO, can be described as a group key. The publisher’s number consists of three elements: a number that identifies the publisher, one that identifies the author, and one that identifies the title. They can be described as a group key, consisting of a separate field for each element if the data source is a VSAM data structure. The Master File looks as follows:

FILE = LIBRARY5, SUFFIX = VSAM,$
SEGMENT = ROOT, SEGTYPE = S0,$
GROUP = BOOKKEY ,ALIAS = KEY ,USAGE = A10 ,ACTUAL = A10 ,$
FIELDNAME = PUBNO ,ALIAS = PN ,USAGE = A3 ,ACTUAL = A3 ,$
FIELDNAME = AUTHNO ,ALIAS = AN ,USAGE = A3 ,ACTUAL = A3 ,$
FIELDNAME = TITLNO ,ALIAS = TN ,USAGE = A4 ,ACTUAL = A4 ,$
FIELDNAME = AUTHOR ,ALIAS = AT ,USAGE = A25 ,ACTUAL = A25 ,$
FIELDNAME = TITLE ,ALIAS = TL ,USAGE = A50 ,ACTUAL = A50 ,$
FIELDNAME = BINDING ,ALIAS = BI ,USAGE = A1 ,ACTUAL = A1 ,$
FIELDNAME = PRICE ,ALIAS = PR ,USAGE = D8.2N ,ACTUAL = D8 ,$
FIELDNAME = SERIAL ,ALIAS = SN ,USAGE = A15 ,ACTUAL = A15 ,$
FIELDNAME = SYNOPSIS ,ALIAS = SY ,USAGE = A150 ,ACTUAL = A150 ,$
FIELDNAME = RECTYPE ,ALIAS = B ,USAGE = A1 ,ACTUAL = A1 ,$
Example: Describing a VSAM Group Field With Multiple Formats

GROUP = A, ALIAS = KEY, USAGE = A14, ACTUAL = A8,$
FIELDNAME = F1, ALIAS = F1, USAGE = P6, ACTUAL=P2,$
FIELDNAME = F2, ALIAS = F2, USAGE = I9, ACTUAL=I4,$
FIELDNAME = F3, ALIAS = F3, USAGE = A2, ACTUAL=A2,$

The lengths of the ACTUAL attributes for subordinate fields F1, F2, and F3 total 8, which is the length of the ACTUAL attribute of the group key. The display lengths of the USAGE attributes for the subordinate fields total 17. However, the length of the group key USAGE attribute is found by adding their internal storage lengths as specified by their field types: 8 for USAGE=P6, 4 for USAGE=I9, and 2 for USAGE=A2, for a total of 14.

Example: Accessing a Group Field With Multiple Formats

When you use a group field with multiple formats in a query, you must account for each position in the group, including trailing blanks or leading zeros. The following example illustrates how to access a group field with multiple formats in a query:

GROUP = GRPB, ALIAS = KEY, USAGE = A8, ACTUAL = A8,$
FIELDNAME = FIELD1, ALIAS = F1, USAGE = A2, ACTUAL = A2,$
FIELDNAME = FIELD2, ALIAS = F2, USAGE = I8, ACTUAL = I4,$
FIELDNAME = FIELD3, ALIAS = F3, USAGE = A2, ACTUAL = A2,$

The values in fields F1 and F3 may include some trailing blanks, and the values in field F2 may include some leading zeros. When using the group in a query, you must account for each position. Because FIELD2 is a numeric field, you cannot specify the IF criteria as follows:

IF GRPB EQ 'A 0334BB'

You can eliminate this error by using a slash (/) to separate the components of the group key:

IF GRPB EQ 'A/334/BB'

Note: Blanks and leading zeros are assumed where needed to fill out the key.

Describe these multiply occurring fields by placing them in a separate segment. Fields A and B are placed in the root segment. Fields C1 and C2, which occur multiply in relation to A and B, are placed in a descendant segment. You use an additional segment attribute, the OCCURS attribute, to specify that these segments represent multiply occurring fields. In certain cases, you may also need a second attribute, called the POSITION attribute.
Using the OCCURS Attribute

**How to:**
Specify a Repeating Field

**Example:**
Using the OCCURS Attribute

The OCCURS attribute is an optional segment attribute used to describe records containing repeating fields or groups of fields. Define such records by describing the singly occurring fields in one segment, and the multiply occurring fields in a descendant segment. The OCCURS attribute appears in the declaration for the descendant segment.

You can have several sets of repeating fields in your data structure. Describe each of these sets of fields as a separate segment in your data source description. Sets of repeating fields can be divided into two basic types: parallel and nested.

**Syntax:** How to Specify a Repeating Field

```
OCCURS = occurstype
```

Possible values for `occurstype` are:

- **n**
  Is an integer value showing the number of occurrences (from 1 to 4095).

- **fieldname**
  Names a field in the parent segment whose integer value contains the number of occurrences of the descendant segment.

- **VARIABLE**
  Indicates that the number of occurrences varies from record to record. The number of occurrences is computed from the record length (for example, if the field lengths for the segment add up to 40, and 120 characters are read in, it means there are three occurrences).

Place the OCCURS attribute in your segment declaration after the PARENT attribute.

When different types of records are combined in one data source, each record type can contain only one segment defined as OCCURS=VARIABLE. It may have OCCURS descendants (if it contains a nested group), but it may not be followed by any other segment with the same parent, that is, there can be no other segments to its right in the hierarchical data structure. This restriction is necessary to ensure that data in the record is interpreted unambiguously.
Example: Using the OCCURS Attribute

Consider the following simple data structure:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C1</th>
<th>C2</th>
<th>C1</th>
<th>C2</th>
</tr>
</thead>
</table>

You have two occurrences of fields C1 and C2 for every one occurrence of fields A and B. Thus, to describe this data source, you place fields A and B in the root segment, and fields C1 and C2 in a descendant segment, as shown here:

Describe this data source as follows:

FILENAME = EXAMPLE1, SUFFIX = FIX, $
SEGNAME = ONE, SEGTYPE=S0, $
FIELDNAME = A, ALIAS=, USAGE = A2, ACTUAL = A2, $
FIELDNAME = B, ALIAS=, USAGE = A1, ACTUAL = A1, $
SEGNAME = TWO, PARENT = ONE, OCCURS = 2, SEGTYPE=S0, $
FIELDNAME = C1, ALIAS=, USAGE = I4, ACTUAL = I2, $
FIELDNAME = C2, ALIAS=, USAGE = I4, ACTUAL = I2, $

Describing a Parallel Set of Repeating Fields

Parallel sets of repeating fields are those that have nothing to do with one another (that is, they have no parent-child or logical relationship). Consider the following data structure:

| A1 | A2 | B1 | B2 | B1 | B2 | C1 | C2 | C1 | C2 | C1 | C2 |
In this example, fields B1 and B2 and fields C1 and C2 repeat within the record. The number of times that fields B1 and B2 occur has nothing to do with the number of times fields C1 and C2 occur. Fields B1 and B2 and fields C1 and C2 are parallel sets of repeating fields. They should be described in the data source description as children of the same parent, the segment that contains fields A1 and A2. The following data structure reflects their relationship.

![Data Structure Diagram]

**Describing a Nested Set of Repeating Fields**

**Example:**

Describing Parallel and Nested Repeating Fields

Nested sets of repeating fields are those whose occurrence depends on one another in some way. Consider the following data structure:

<table>
<thead>
<tr>
<th>A1</th>
<th>A2</th>
<th>B1</th>
<th>B2</th>
<th>C1</th>
<th>C1</th>
<th>B1</th>
<th>B2</th>
<th>C1</th>
<th>C1</th>
<th>C1</th>
</tr>
</thead>
</table>

Using the Adapter for VSAM
In this example, field C1 only occurs after fields B1 and B2 occur once. It occurs varying numbers of times, recorded by a counter field, B2. There is not a set of occurrences of C1 which is not preceded by an occurrence of fields B1 and B2. Fields B1, B2, and C1 are a nested set of repeating fields. They can be represented by the following data structure:

Since field C1 repeats with relation to fields B1 and B2, which repeat in relation to fields A1 and A2, field C1 is described as a separate, descendant segment of Segment TWO, which is in turn a descendant of Segment ONE.

**Example: Describing Parallel and Nested Repeating Fields**

The following data structure contains both nested and parallel sets of repeating fields.
It produces the following data structure:

```
FILENAME = EXAMPLE3, SUFFIX = FIX,$
SEGNAME = ONE,   SEGTYPE=S0,$
   FIELDNAME = A1 ,ALIAS= ,ACTUAL = A1  ,USAGE = A1  ,$
   FIELDNAME = A2 ,ALIAS= ,ACTUAL = I1  ,USAGE = I1  ,$
SEGNAME = TWO,   SEGTYPE=S0, PARENT = ONE, OCCURS = 2  ,$
   FIELDNAME = B1 ,ALIAS= ,ACTUAL = A15, USAGE = A15, $
   FIELDNAME = B2 ,ALIAS= ,ACTUAL = I1  ,USAGE = I1  ,$
SEGNAME = THREE, SEGTYPE=S0, PARENT = TWO, OCCURS = B2 ,$
   FIELDNAME = C1 ,ALIAS= ,ACTUAL = A25, USAGE = A25, $
SEGNAME = FOUR, SEGTYPE=S0, PARENT = ONE, OCCURS = A2   ,$
   FIELDNAME = D1 ,ALIAS= ,ACTUAL = A15, USAGE = A15, $
SEGNAME = FIVE, SEGTYPE=S0, PARENT = ONE, OCCURS = VARIABLE, $
   FIELDNAME = E1 ,ALIAS= ,ACTUAL = A5  ,USAGE = A5  ,$
```

Describe this data source as follows. Notice that the assignment of the PARENT attributes shows you how the occurrences are nested.
Note:

- Segments ONE, TWO, and THREE represent a nested group of repeating segments. Fields B1 and B2 occur a fixed number of times, so OCCURS equals 2. Field C1 occurs a certain number of times within each occurrence of fields B1 and B2. The number of times C1 occurs is determined by the value of field B2, which is a counter. In this case, its value is 3 for the first occurrence of Segment TWO and 4 for the second occurrence.

- Segments FOUR and FIVE consist of fields that repeat independently within the parent segment. They have no relationship to each other or to Segment TWO except their common parent, so they represent a parallel group of repeating segments.

- As in the case of Segment THREE, the number of times Segment FOUR occurs is determined by a counter in its parent, A2. In this case, the value of A2 is two.

- The number of times Segment FIVE occurs is variable. This means that all the rest of the fields in the record (all those to the right of the first occurrence of E1) are read as recurrences of field E1. To ensure that data in the record is interpreted unambiguously, a segment defined as OCCURS=VARIABLE must be at the end of the record. In a data structure diagram, it is the rightmost segment. Note that there can be only one segment defined as OCCURS=VARIABLE for each record type.

Using the POSITION Attribute

**How to:**

Specify the Position of a Repeating Field

**Example:**

Specifying the Position of a Repeating Field

The POSITION attribute is an optional attribute used to describe a structure in which multiply occurring fields with an established number of occurrences are located in the middle of the record. You describe the data source as a hierarchical structure, made up of a parent segment and at least one child segment that contains the multiply occurring fields. The parent segment is made up of whatever singly occurring fields are in the record, as well as one or more alphanumeric fields that appear where the multiply occurring fields appear in the record. The alphanumeric field may be a dummy field that is the exact length of the combined multiply occurring fields. For example, if you have four occurrences of an 8-character field, the length of the field in the parent segment is 32 characters.

You can also use the POSITION attribute to re-describe fields with SEGTYPE=U. See *Redefining a Field in a VSAM Data Source* on page 2601.
**Syntax:** How to Specify the Position of a Repeating Field

The POSITION attribute is described in the child segment. It gives the name of the field in the parent segment that specifies the starting position and overall length of the multiply occurring fields. The syntax of the POSITION attribute is

\[
\text{POSITION} = \text{fieldname}
\]

where:

- **fieldname**
  
  Is the name of the field in the parent segment that defines the starting position of the multiple field occurrences.

**Example:** Specifying the Position of a Repeating Field

Consider the following data structure:

<table>
<thead>
<tr>
<th>A1</th>
<th>Q1</th>
<th>Q1</th>
<th>Q1</th>
<th>Q1</th>
<th>A2</th>
<th>A3</th>
<th>A4</th>
</tr>
</thead>
</table>

In this example, field Q1 repeats four times in the middle of the record. When you describe this structure, you specify a field or fields that occupy the position of the four Q1 fields in the record. You then assign the actual Q1 fields to a multiply occurring descendant segment. The POSITION attribute, specified in the descendant segment, gives the name of the field in the parent segment that identifies the starting position and overall length of the Q fields.

Use the following Master File to describe this structure:

```plaintext
FILENAME = EXAMPLE3, SUFFIX = FIX,$
SEGNAME = ONE, SEGTYPE=S0,$
    FIELDNAME = A1   ,ALIAS= ,USAGE = A14 ,ACTUAL = A14 ,$
    FIELDNAME = QFIL ,ALIAS= ,USAGE = A32 ,ACTUAL = A32 ,$
    FIELDNAME = A2   ,ALIAS= ,USAGE = I2  ,ACTUAL = I2  ,$
    FIELDNAME = A3   ,ALIAS= ,USAGE = A10 ,ACTUAL = A10 ,$
    FIELDNAME = A4   ,ALIAS= ,USAGE = A15 ,ACTUAL = A15 ,$
SEGNAME = TWO, SEGTYPE=S0, PARENT = ONE, POSITION = QFIL, OCCURS = 4 ,$
    FIELDNAME = Q1   ,ALIAS= ,USAGE = D8  ,ACTUAL = D8  ,$
```
This produces the following structure:

If the total length of the multiply occurring fields is longer than 4095, you can use a filler field after the dummy field to make up the remaining length. This is required, because the format of an alphanumeric field cannot exceed 4095 bytes.

Notice that this structure works only if you have a fixed number of occurrences of the repeating field. This means the OCCURS attribute of the descendant segment must be of the type OCCURS=n. OCCURS=fieldname or OCCURS=VARIABLE does not work.

Specifying the ORDER Field

**How to:**
Specify the Sequence of a Repeating Field

In an OCCURS segment, the order of the data may be significant. For example, the values may represent monthly or quarterly data, but the record itself may not explicitly specify the month or quarter to which the data applies.

To associate a sequence number with each occurrence of the field, you may define an internal counter field in any OCCURS segment. A value is automatically supplied that defines the sequence number of each repeating group.

**Syntax:**
**How to Specify the Sequence of a Repeating Field**

The syntax rules for an ORDER field are:

- It must be the last field described in an OCCURS segment.
- The field name is arbitrary.
- The ALIAS is ORDER.
- The USAGE is In, with any appropriate edit options.
The ACTUAL is I4.

For example:

FIELD = ACT_MONTH, ALIAS = ORDER, USAGE = I2MT, ACTUAL = I4, $

Order values are 1, 2, 3, and so on, within each occurrence of the segment. The value is assigned prior to any selection tests that might accept or reject the record, and so it can be used in a selection test.

For example, to obtain data for only the month of June, type:

SUM AMOUNT...
WHERE ACT_MONTH IS 6

The ORDER field is a virtual field used internally. It does not alter the logical record length (LRECL) of the data source being accessed.

Redefining a Field in a VSAM Data Source

How to:
Redefine a Field

Example:
Redefining a VSAM Structure

Reference:
Special Considerations for Redefining a Field

Redefining record fields in non-FOCUS data sources is supported. This enables you to describe a field with an alternate layout.

Within the Master File, the redefined fields must be described in a separate unique segment (SEGTYPE=U) using the POSITION=fieldname and OCCURS=1 attributes.

The redefined fields can have any user-defined name.

Syntax: How to Redefine a Field

SEGNAME = segname, SEGTYPE = U, PARENT = parentseg,
OCCURS = 1, POSITION = fieldname,$

where:

segname

Is the name of the segment.
Redefining a Field in a VSAM Data Source

parentseg

Is the name of the parent segment.

fieldname

Is the name of the first field being redefined. Using the unique segment with redefined fields helps avoid problems with multipath reporting.

A one-to-one relationship forms between the parent record and the redefined segment.

Example: Redefining a VSAM Structure

The following example illustrates redefinition of the VSAM structure described in the COBOL file description, where the COBOL FD is:

```cobol
01 ALLFIELDS
   02 FLD1   PIC X(4)         - this describes alpha/numeric data
   02 FLD2   PIC X(4)         - this describes numeric data
   02 RFLD1  PIC 9(5)V99 COMP-3 REDEFINES FLD2
   02 FLD3   PIC X(8)         - this describes alpha/numeric data

FILE = REDEF, SUFFIX = VSAM,$
SEGNAME = ONE, SEGTYPE = S0,$
GROUP = RKEY, ALIAS = KEY, USAGE = A4 ,ACTUAL = A4 ,$
   FIELDNAME = FLD1,, USAGE = A4 ,ACTUAL = A4 ,$
   FIELDNAME = FLD2,, USAGE = A4 ,ACTUAL = A4 ,$
   FIELDNAME = FLD3,, USAGE = A8 ,ACTUAL = A8 ,$
SEGNAME = TWO, SEGTYPE = U, POSITION = FLD2, OCCURS = 1, PARENT = ONE ,$
   FIELDNAME = RFLD1,, USAGE = P8.2 ,ACTUAL = Z4 ,$
```

Reference: Special Considerations for Redefining a Field

- Redefinition is a read-only feature and is used only for presenting an alternate view of the data. It is not used for changing the format of the data.

- For non-alphanumeric fields, you must know your data. Attempts to print numeric fields that contain alphanumeric data produce data exceptions or errors converting values. It is recommended that the first definition always be alphanumeric to avoid conversion errors.

- More than one field can be redefined in a segment.

- Redefines are supported only for IDMS, IMS, VSAM, DB2, and FIX data sources.
Extra-Large Record Length Support

**How to:**
Define the Maximum Record Length

If the Master File describes a data source with OCCURS segments, and if the longest single record in the data source is larger than 16K bytes, it is necessary to specify a larger record size in advance.

**Syntax:**

**How to Define the Maximum Record Length**

```plaintext
SET MAXLRECL = nnnnn
```

where:

- `nnnnn` is up to 32768.

For example, `SET MAXLRECL=12000` allows handling of records that are 12000 bytes long. Once you have entered the `SET MAXLRECL` command, you can obtain the current value of the MAXLRECL parameter by using the `? SET MAXLRECL` command.

If the actual record length is longer than specified, retrieval halts and the actual record length appears in hexadecimal notation.

Describing Multiple Record Types

**In this section:**
- Describing a RECTYPE Field
- Describing Positionally Related Records
- Ordering of Records in the Data Source
- Describing Unrelated Records
- Using a Generalized Record Type

VSAM, data sources can contain more than one type of record. When they do, they can be structured in one of two ways:

- A positional relationship may exist between the various record types, with a record of one type being followed by one or more records containing detailed information about the first record.
If a positional relationship exists between the various record types, with a parent record of one type followed by one or more child records containing detail information about the parent, you describe the structure by defining the parent as the root, and the detail segments as descendants.

Some VSAM data sources are structured so that descendant records relate to each other through concatenating key fields. That is, the key fields of a parent record serve as the first part of the key of a child record. In such cases, the segment key fields must be described using a GROUP declaration. The GROUP key fields of each segment consist of the renamed key fields from the parent segment plus the unique key field from the child record.

The records have no meaningful positional relationship, and records of varying types exist independently of each other in the data source.

If the records have no meaningful positional relationship, you have to provide some means for interpreting the type of record that has been read. Do this by creating a dummy root segment for the records.

Key-sequenced VSAM data sources also use the RECTYPE attribute to distinguish various record types within the data source.

A parent does not always share its RECTYPE with its descendants. It may share some other identifying piece of information, such as the PUBNO in the example. This is the field that should be included in the parent key, as well as all of its descendants keys, to relate them.

When using the RECTYPE attribute in VSAM data sources with group keys, the RECTYPE field can be part of the segment's group key only when it belongs to a segment that has no descendants, or to a segment whose descendants are described with an OCCURS attribute. In *Describing VSAM Positionally Related Records* on page 2609, the RECTYPE field is added to the group key in the SERIANO segment, the lowest descendant segment in the chain.
Describing a RECTYPE Field

How to:
Specify a Record Type Field

Example:
Specifying the RECTYPE Field

When a data source contains multiple record types, there must be a field in the records themselves that can be used to differentiate between the record types. You can find information on this field in your existing description of the data source (for example, a COBOL FD statement). This field must appear in the same physical location of each record. For example, columns 79 and 80 can contain a different 2-digit code for each unique record type. Describe this identifying field with the field name RECTYPE.

Another technique for redefining the parts of records is to use the MAPFIELD and MAPVALUE attributes described in Describing a Repeating Group Using MAPFIELD on page 2622.

Syntax:  How to Specify a Record Type Field

The RECTYPE field must fall in the same physical location of each record in the data source, or the record is ignored. The syntax to describe the RECTYPE field is

```
FIELDNAME = RECTYPE, ALIAS = value, USAGE = format, ACTUAL = format, ACCEPT = {list|range},$
```

where:

value

Is the record type in alphanumeric format, if an ACCEPT list is not specified. If there is an ACCEPT list, this can be any value.

format

Is the data type of the field. In addition to RECTYPE fields in alphanumeric format, RECTYPE fields in packed and integer formats (formats P and I) are supported. Possible values are:

An

Where \( n \) is 1-4095. Indicates character data, including letters, digits, and other characters.

In

Indicates ACTUAL (internal) format binary integers:

- \( I1 \) = single-byte binary integer.
I2 = half-word binary integer (2 bytes).
I4 = full-word binary integer (4 bytes).

The USAGE format can be I1 through I9, depending on the magnitude of the ACTUAL format.

Pn
Where n is 1-16. Indicates packed decimal ACTUAL (internal) format. n is the number of bytes, each of which contains two digits, except for the last byte which contains a digit and the sign. For example, P6 means 11 digits plus a sign.

If the field contains an assumed decimal point, represent the field with a USAGE format of Pm.n, where m is the total number of digits, and n is the number of decimal places. Thus, P11.1 means an 11-digit number with one decimal place.

list
Is a list of one or more lines of specific RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the list is 255. Separate each item in the list with either a blank or the keyword OR. If the list contains embedded blanks or commas, it must be enclosed within single quotation marks. The list may contain a single RECTYPE value. For example:

FIELDNAME = RECTYPE, ALIAS = TYPEABC, USAGE = A1, ACTUAL = A1, ACCEPT = A OR B OR C, $

range
Is a range of one or more lines of RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the range is 255. If the range contains embedded blanks or commas, it must be enclosed within single quotation marks.

To specify a range of values, include the lowest value, the keyword TO, and the highest value, in that order. For example:

FIELDNAME = RECTYPE, ALIAS = ACCTREC, USAGE = P3, ACTUAL = P2, ACCEPT = 100 TO 200, $

Example: Specifying the RECTYPE Field

The following field description is of a 1 byte packed RECTYPE field containing the value 1:

FIELD = RECTYPE, ALIAS = 1, USAGE = P1, ACTUAL = P1, $

The following field description is of a 3 byte alphanumeric RECTYPE field containing the value A34:

FIELD = RECTYPE, ALIAS = A34, USAGE = A3, ACTUAL = A3,$
Describing Positionally Related Records

The following diagram shows a more complex version of the library data source:

![Diagram of library data source]

Information that is common to all copies of a given book (the identifying number, the author’s name, and its title) has the same record type. All of this information is assigned to the root segment in the Master File. The synopsis is common to all copies of a given book, but in this data source it is described as a series of repeating fields of ten characters each, in order to save space.

The synopsis is assigned to its own subordinate segment with an attribute of OCCURS=VARIABLE in the Master File. Although there are segments in the diagram to the right of the OCCURS=VARIABLE segment, OCCURS=VARIABLE is the rightmost segment within its own record type. Only segments with a RECTYPE that is different from the OCCURS=VARIABLE segment can appear to its right in the structure. Note also that the OCCURS=VARIABLE segment does not have a RECTYPE. This is because it is part of the same record as its parent segment.

Binding and price can vary among copies of a given title. For instance, the library may have two different versions of Pamela, one a paperback costing $7.95, the other a hardcover costing $15.50. These two fields are of a second record type, and are assigned to a descendant segment in the Master File.

Finally, every copy of the book in the library has its own identifying serial number, which is described in a field of record type S. In the Master File, this information is assigned to a segment that is a child of the segment containing the binding and price information.
Use the following Master File to describe this data source:

```
FILENAME = LIBRARY2, SUFFIX = FIX,$
SEGNAME = PUBINFO, SEGTYPE = S0,$
  FIELDNAME = RECTYPE ,ALIAS = P     ,USAGE = A1    ,ACTUAL = A1  ,$
  FIELDNAME = PUBNO    ,ALIAS = PN    ,USAGE = A10   ,ACTUAL = A10 ,$
  FIELDNAME = AUTHOR   ,ALIAS = AT    ,USAGE = A25   ,ACTUAL = A25 ,$
  FIELDNAME = TITLE    ,ALIAS = TL    ,USAGE = A50   ,ACTUAL = A50 ,$
SEGNAME = SYNOPSIS, PARENT = PUBINFO, OCCURS = VARIABLE, SEGTYPE = S0,$
  FIELDNAME = PLOTLINE ,ALIAS = PLOTL ,USAGE = A10   ,ACTUAL = A10 ,$
SEGNAME = BOOKINFO, PARENT = PUBINFO, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = B     ,USAGE = A1    ,ACTUAL = A1  ,$
  FIELDNAME = BINDING  ,ALIAS = BI    ,USAGE = A1    ,ACTUAL = A1  ,$
  FIELDNAME = PRICE    ,ALIAS = PR    ,USAGE = D8.2N ,ACTUAL = D8  ,$
SEGNAME = SERIANO, PARENT = BOOKINFO, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = S     ,USAGE = A1    ,ACTUAL = A1  ,$
  FIELDNAME = SERIAL   ,ALIAS = SN    ,USAGE = A15   ,ACTUAL = A15 ,$
```

Note that each segment, except OCCURS, contains a field named RECTYPE and that the ALIAS for the field contains a unique value for each segment (P, B, and S). If there is a record in this data source with a RECTYPE other than P, B, or S, the record is ignored. The RECTYPE field must fall in the same physical location in each record.

**Ordering of Records in the Data Source**

**Example:**

Describing VSAM Positionally Related Records

Physical order determines parent/child relationships in sequential records. Every parent record does not need descendants. Specify how you want data in missing segment instances handled in your reports by using the SET command to change the ALL parameter.

In the example in *Describing Positionally Related Records* on page 2607, if the first record in the data source is not a PUBINFO record, the record is considered to be a child without a parent. Any information allotted to the SYNOPSIS segment appears in the PUBINFO record. The next record may be a BOOKINFO or even another PUBINFO (in which case the first PUBINFO is assumed to have no descendants). Any SERIANO records are assumed to be descendants of the previous BOOKINFO record. If a SERIANO record follows a PUBINFO record with no intervening BOOKINFO, it is treated as if it has no parent.
**Example: Describing VSAM Positionally Related Records**

Consider the following VSAM data source that contains three types of records. The ROOT records have a key that consists of the publisher's number, PUBNO. The BOOKINFO segment has a key that consists of that same publisher number, plus a hard-cover or soft-cover indicator, BINDING. The SERIANO segment key consists of the first two elements, plus a record type field, RECTYPE.

FILENAME = LIBRARY6, SUFFIX = VSAM,$
SEGNAME = ROOT, SECTYPE = S0,$
    GROUP=PUBKEY ,ALIAS=KEY ,USAGE=A10 ,ACTUAL=A10 ,$
    FIELDNAME=PUBNO ,ALIAS=PN ,USAGE=A10 ,ACTUAL=A10 ,$
    FIELDNAME=FILLER ,ALIAS= ,USAGE=A1 ,ACTUAL=A1 ,$
    FIELDNAME=RECTYPE ,ALIAS=1 ,USAGE=A1 ,ACTUAL=A1 ,$
    FIELDNAME.AUTHOR ,ALIAS=AT ,USAGE=A25 ,ACTUAL=A25 ,$
    FIELDNAME.TITLE ,ALIAS=TL ,USAGE=A50 ,ACTUAL=A50 ,$
SEGNAME=BOOKINFO,PARENT=ROOT, SECTYPE=S0,$
    GROUP=BOINKEY ,ALIAS=KEY ,USAGE=A11 ,ACTUAL=A11 ,$
    FIELDNAME=PUBNO1 ,ALIAS=P1 ,USAGE=A10 ,ACTUAL=A10 ,$
    FIELDNAME=BINDING ,ALIAS=BI ,USAGE=A1 ,ACTUAL=A1 ,$
    FIELDNAME=RECTYPE ,ALIAS=2 ,USAGE=A1 ,ACTUAL=A1 ,$
    FIELDNAME.PRICE ,ALIAS=PR ,USAGE=D8.2N ,ACTUAL=D8 ,$
SEGNAME=SERIANO, PARENT=BOOKINFO, SECTYPE=S0,$
    GROUP=SERIKEY ,ALIAS=KEY ,USAGE=A12 ,ACTUAL=A12 ,$
    FIELDNAME=PUBNO2 ,ALIAS=P2 ,USAGE=A10 ,ACTUAL=A10 ,$
    FIELDNAME=BINDING1 ,ALIAS=B1 ,USAGE=A1 ,ACTUAL=A1 ,$
    FIELDNAME=RECTYPE ,ALIAS=3 ,USAGE=A1 ,ACTUAL=A1 ,$
    FIELDNAME=SERIAL ,ALIAS=SN ,USAGE=A15 ,ACTUAL=A15 ,$
SEGNAME=SYNOPSIS,PARENT=ROOT, SECTYPE=S0, OCCURS=VARIABLE,$
    FIELDNAME=PLOTLINE ,ALIAS=PLOTL ,USAGE=A10 ,ACTUAL=A10 ,$

Notice that the length of the key fields specified in the USAGE and ACTUAL attributes of a GROUP declaration is the length of the key fields from the parent segments, plus the length of the added field of the child segment (RECTYPE field). In the example above, the length of the GROUP key SERIKEY equals the length of PUBNO2 and BINDING1, the group key from the parent segment, plus the length of RECTYPE, the field added to the group key in the child segment. The length of the key increases as you traverse the structure.

**Note:** Each segment key describes as much of the true key as needed to find the next instance of that segment.
In the sample data source, the repetition of the publisher number as PUBNO1 and PUBNO2 in the descendant segments interrelates the three types of records. The data source can be diagrammed as the following structure:

A typical query may request information on price and call numbers for a specific publisher’s number:

```
PRINT PRICE AND SERIAL BY PUBNO
IF PUBNO EQ 1234567890 OR 9876054321
```

Since PUBNO is part of the key, retrieval can occur quickly, and the processing continues. To further speed retrieval, add search criteria based on the BINDING field, which is also part of the key.
Describing Unrelated Records

Example:
Describing Unrelated Records Using a Dummy Root Segment
Describing a VSAM Data Source With Unrelated Records
Describing a Key and a Record Type for a VSAM Data Source With Unrelated Records

Some VSAM data sources do not have records that are related to one another. That is, the VSAM key of one record type is independent of the keys of other record types. To describe data sources with unrelated records, define a dummy root segment for the record types. The following rules apply to the dummy root segment:

- The name of the root segment must be DUMMY.
- It must have only one field with a blank name and alias.
- The USAGE and ACTUAL attributes must both be A1.

All other non-repeating segments must point to the dummy root as their parent. Except for the root, all non-repeating segments must have a RECTYPE and a PARENT attribute and describe the full VSAM key. If the data source does not have a key, the group should not be described. RECTYPEs may be anywhere in the record.

Example: Describing Unrelated Records Using a Dummy Root Segment

The library data source has three types of records: book information, magazine information, and newspaper information. Since these three record types have nothing in common, they cannot be described as parent records followed by detail records.

The data source can look like this:

- BOOK
- MAGAZINE
- NEWSPAPER
A structure such as the following can also describe this data source:

![Diagram showing the structure of data segments: DUMMY, BOOK, MAGAZINE, NEWSPAP, with fields like RECTYPE, PUBNO, TITLE, BINDING, PRICE, SERIAL, SYNOPSIS, PER_NO, PER_NAME, VOL_NO, NEW_NAME, NEW_DATE, NVOL_NO.]

The Master File for the structure in this example is:

FILENAME = LIBRARY3, SUFFIX = FIX,$
SEGMENT = DUMMY, SEGTYPE = S0,$
  FIELDNAME= ,ALIAS= ,USAGE = A1 ,ACTUAL = A1 ,$
SEGMENT = BOOK, PARENT = DUMMY, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = B  ,USAGE = A1    ,ACTUAL = A1   ,$
  FIELDNAME = PUBNO    ,ALIAS = PN ,USAGE = A10   ,ACTUAL = A10  ,$
  FIELDNAME = AUTHOR   ,ALIAS = AT ,USAGE = A25   ,ACTUAL = A25  ,$
  FIELDNAME = TITLE    ,ALIAS = TL ,USAGE = A50   ,ACTUAL = A50  ,$
  FIELDNAME = BINDING  ,ALIAS = BI ,USAGE = A1    ,ACTUAL = A1   ,$
  FIELDNAME = PRICE    ,ALIAS = PR ,USAGE = D8.2N ,ACTUAL = D8   ,$
  FIELDNAME = SERIAL   ,ALIAS = SN ,USAGE = A15   ,ACTUAL = A15  ,$
  FIELDNAME = SYNOPSIS ,ALIAS = SY ,USAGE = A150 ,ACTUAL = A150 ,$
SEGMENT = MAGAZINE, PARENT = DUMMY, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = M  ,USAGE = A1    ,ACTUAL = A1   ,$
  FIELDNAME = PER_NO   ,ALIAS = PN ,USAGE = A10   ,ACTUAL = A10  ,$
  FIELDNAME = PER_NAME ,ALIAS = NA ,USAGE = A50   ,ACTUAL = A50  ,$
  FIELDNAME = VOL_NO   ,ALIAS = VN ,USAGE = I2    ,ACTUAL = I2   ,$

  FIELDNAME = NEW_DATE ,ALIAS = ND ,USAGE = I6MDY,ACTUAL = I6   ,$
  FIELDNAME = NVOL_NO  ,ALIAS = NV ,USAGE = I2    ,ACTUAL = I2   ,$
  FIELDNAME = ISSUE    ,ALIAS = NI ,USAGE = I2    ,ACTUAL = I2   ,$

**Example:** Describing a VSAM Data Source With Unrelated Records

Consider another VSAM data source containing information on the library. This data source has three types of records: book information, magazine information, and newspaper information.
There are two possible structures:

- The RECTYPE is the beginning of the key. The key structure is:
  
<table>
<thead>
<tr>
<th>RECTYPE</th>
<th>Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Book Code</td>
</tr>
<tr>
<td>M</td>
<td>Magazine Code</td>
</tr>
<tr>
<td>N</td>
<td>Newspaper Code</td>
</tr>
</tbody>
</table>

  The sequence of records is:
  Book
  Book
  Magazine
  Magazine
  Newspaper
  Newspaper

  Note the difference between the use of the RECTYPE here and its use when the records are positionally related. In this case, the codes are unrelated and the database designer has chosen to accumulate the records by type first (all the book information together, all the magazine information together, and all the newspaper information together), so the RECTYPE may be the initial part of the key.

- The RECTYPE is not in the beginning of the key or is outside of the key. The key structure is:
  
  Book Code
  Magazine Code
  Newspaper Code

  The sequence of record types in the data source can be arbitrary.

  Both types of file structure can be represented by the following:
Describing Multiple Record Types

**Example:** Describing a Key and a Record Type for a VSAM Data Source With Unrelated Records

Using a Generalized Record Type

**How to:**
Specify a Generalized Record Type

**Example:**
Using a Generalized Record Type

If your VSAM data source has multiple record types that share the same layout, you can specify a single generalized segment that describes all record types that have the common layout. By using a generalized segment, also known as a generalized RECTYPE, instead of one segment per record type, you reduce the number of segments you need to describe in the Master File.
When using a generalized segment, you identify RECTYPE values using the ACCEPT attribute. You can assign any value to the ALIAS attribute.

**Syntax:**  
**How to Specify a Generalized Record Type**

FIELDNAME = RECTYPE, ALIAS = alias, USAGE = format, ACTUAL = format, 
ACCEPT = {list|range}, $

where:

**RECTYPE**

Is the required field name.

**Note:** Since the field name, RECTYPE, may not be unique across segments, you should not use it in this way unless you qualify it. An alias is not required; you may leave it blank.

**alias**

Is any valid alias specification. You can specify a unique name as the alias value for the RECTYPE field only if you use the ACCEPT attribute. The alias can then be used in a TABLE request as a display field, a sort field, or in selection tests using either WHERE or IF.

**list**

Is a list of one or more lines of specific RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the list is 255. Each item in the list must be separated by either a blank or the keyword OR. If the list contains embedded blanks or commas, it must be enclosed within single quotation marks. The list may contain a single RECTYPE value. For example:

FIELDNAME = RECTYPE, ALIAS = TYPEABC, USAGE = A1, 
ACTUAL = A1, ACCEPT = A OR B OR C, $

**range**

Is a range of one or more lines of RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the range is 255. If the range contains embedded blanks or commas, it must be enclosed within single quotation marks.

To specify a range of values, include the lowest value, the keyword TO, and the highest value, in that order. For example:

FIELDNAME = RECTYPE, ALIAS = ACCTREC, USAGE = P3, 
ACTUAL = P2, ACCEPT = 100 TO 200, $
**Example:** Using a Generalized Record Type

To illustrate the use of the generalized record type in a VSAM Master File, consider the following record layouts in the DOC data source. Record type DN is the root segment and contains the document number and title. Record types M, I, and C contain information about manuals, installation guides, and course guides, respectively. Notice that record types M and I have the same layout.

Record type DN:

---KEY---
+-----------------------------------------------------------------------+
DOCID   FILLER            RECTYPE     TITLE
+-----------------------------------------------------------------------+

Record type M:

--------KEY--------
+-----------------------------------------------------------------------+
MDOCID   MDATE            RECTYPE     MRELEASE          MPAGES     FILLER
+-----------------------------------------------------------------------+

Record type I:

--------KEY--------
+-----------------------------------------------------------------------+
IDOCID   IDATE            RECTYPE     IRELEASE          IPAGES     FILLER
+-----------------------------------------------------------------------+

Record type C:

--------KEY--------
+-----------------------------------------------------------------------+
CRSEDOC   CDATE           RECTYPE     COURSENUM  LEVEL  CPAGES     FILLER
+-----------------------------------------------------------------------+

Without the ACCEPT attribute, each of the four record types must be described as separate segments in the Master File. A unique set of field names must be provided for record type M and record type I, although they have the same layout.
The generalized RECTYPE capability enables you to code just one set of field names that applies to the record layout for both record type M and I. The ACCEPT attribute can be used for any RECTYPE specification, even when there is only one acceptable value.

```

Combining Multiply-Occurring Fields and Multiple Record Types

In this section:

- Describing a Multiply Occurring Field and Multiple Record Types
- Describing a VSAM Repeating Group With RECTYPEs
- Describing a Repeating Group Using MAPFIELD

You can have two types of descendant segments in a single fixed-format, VSAM data source:

- Descendant segments consisting of multiply occurring fields.
- Additional descendant segments consisting of multiple record types.
Describing a Multiply Occurring Field and Multiple Record Types

In the data structure shown below, the first record, of type 01, contains several different sequences of repeating fields, all of which must be described as descendant segments with an OCCURS attribute. The data source also contains two separate records, of types 02 and 03, which contain information that is related to that in record type 01.

The relationship between the records of various types is expressed as parent-child relationships. The children that contain record types 02 and 03 do not have an OCCURS attribute. They are distinguished from their parent by the field declaration where field=RECTYPE.

The description for this data source is:

FILENAME = EXAMPLE1, SUFFIX = FIX,$
SEGNAME = A, SEGTYPE=S0,$
FIELDNAME = RECTYPE ,ALIAS = 01 ,USAGE = A2 ,ACTUAL = A2 ,$
FIELDNAME = T1 ,ALIAS = ,USAGE = A2 ,ACTUAL = A1 ,$
FIELDNAME = N1 ,ALIAS = ,USAGE = A1 ,ACTUAL = A1 ,$
SEGNAME = B, PARENT = A, OCCURS = VARIABLE, SEGTYPE=S0,$
FIELDNAME = B1 ,ALIAS = ,USAGE = I2 ,ACTUAL = I2 ,$
FIELDNAME = B2 ,ALIAS = ,USAGE = I2 ,ACTUAL = I2 ,$
SEGNAME = C, PARENT = B, OCCURS = B1, SEGTYPE=S0,$
FIELDNAME = C1 ,ALIAS = ,USAGE = A1 ,ACTUAL = A1 ,$
SEGNAME = D, PARENT = B, OCCURS = 7, SEGTYPE=S0,$
FIELDNAME = D1 ,ALIAS = ,USAGE = A1 ,ACTUAL = A1 ,$
SEGNAME = E, PARENT = A, SEGTYPE=S0,$
FIELDNAME = RECTYPE ,ALIAS = 02 ,USAGE = A2 ,ACTUAL = A2 ,$
FIELDNAME = E1 ,ALIAS = ,USAGE = A1 ,ACTUAL = A1 ,$
SEGNAME = F, PARENT = E, SEGTYPE=S0,$
FIELDNAME = RECTYPE ,ALIAS = 03 ,USAGE = A2 ,ACTUAL = A2 ,$
FIELDNAME = F1 ,ALIAS = ,USAGE = A1 ,ACTUAL = A1 ,$

Combining Multiply-Occurring Fields and Multiple Record Types
It produces the following data structure:

Segments A, B, C, and D all belong to the same record type. Segments E and F each are stored as separate record types.
Note:

- Segments A, E, and F are different records that are related through their record types. The record type attribute consists of certain prescribed values, and is stored in a fixed location in the records. Records are expected to be retrieved in a given order. If the first record does not have a RECTYPE of 01, the record is considered to be a child without a parent. The next record can have a RECTYPE of either 01 (in which case, the first record is considered to have no descendants except the OCCURS descendants) or 02. A record with a RECTYPE of 03 can follow only a record with a RECTYPE of 02 (its parent) or another 03.

- The OCCURS descendants all belong to the record whose RECTYPE is 01. (This is not a necessary condition; records of any type can have OCCURS descendants.) Note that the OCCURS=VARIABLE segment, Segment B, is the rightmost segment within its own record type. If you look at the data structure, the pattern that makes up Segment B and its descendants (the repetition of fields B1, B2, C1, and D1) extends from the first mention of fields B1 and B2 to the end of the record.

- Although fields C1 and D1 appear in separate segments, they are actually part of the repeating pattern that makes up the OCCURS=VARIABLE segment. Since they occur multiple times within Segment B, they are each assigned to their own descendant segment. The number of times field C1 occurs depends on the value of field B2. In the example, the first value of field B2 is 3; the second, 2. Field D1 occurs a fixed number of times, 7.

**Describing a VSAM Repeating Group With RECTYPEs**

**Example:**

Describing a VSAM Repeating Group With RECTYPEs

Suppose you want to describe a data source that, schematically, looks like this:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>RECTYPE</th>
<th>B</th>
<th>C</th>
<th></th>
<th></th>
<th>RECTYPE</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td></td>
<td>RECTYPE</td>
<td>B</td>
<td>C</td>
<td></td>
<td></td>
<td>RECTYPE</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>A</td>
<td></td>
<td>RECTYPE</td>
<td>D</td>
<td></td>
<td></td>
<td></td>
<td>RECTYPE</td>
<td>D</td>
<td></td>
</tr>
</tbody>
</table>

2620 WebFOCUS
You need to describe three segments in your Master File, with A as the root segment, and segments for B, C, and D as two descendant OCCURS segments for A:

Each of the two descendant OCCURS segments in this example depends on the RECTYPE indicator that appears for each occurrence.

All the rules of syntax for using RECTYPE fields and OCCURS segments also apply to RECTYPEs within OCCURS segments.

Since each OCCURS segment depends on the RECTYPE indicator for its evaluation, the RECTYPE must appear at the start of the OCCURS segment. This enables you to describe complex data sources, including those with nested and parallel repeating groups that depend on RECTYPEs.

**Example:** **Describing a VSAM Repeating Group With RECTYPEs**

In this example, B/C, and D represent a nested repeating group, and E represents a parallel repeating group.
Describing a Repeating Group Using MAPFIELD

**How to:**

Describe a Repeating Group With MAPFIELD

Use MAPFIELD for a Descendant Repeating Segment in a Repeating Group

**Example:**

Using MAPFIELD and MAPVALUE

In another combination of record indicator and OCCURS, a record contains a record indicator that is followed by a repeating group. In this case, the record indicator is in the fixed portion of the record, not in each occurrence. Schematically, the record appears like this:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>record indicator (1)</th>
<th>C</th>
<th>D</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>record indicator (2)</td>
<td>E</td>
<td>E</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The first record contains header information, values for A and B, followed by an OCCURS segment of C and D that was identified by its preceding record indicator. The second record has a different record indicator and contains a different repeating group, this time for E.
The following diagram illustrates this relationship.

Since the OCCURS segments are identified by the record indicator rather than the parent A/B segment, you must use the keyword MAPFIELD. MAPFIELD identifies a field in the same way as RECTYPE, but since each OCCURS segments has its own value for MAPFIELD, the value of MAPFIELD is associated with each OCCURS segment by means of a complementary field named MAPVALUE.

The following diagram illustrates this relationship.

MAPFIELD is assigned as the ALIAS of the field that is the record indicator; it may have any name.
**Syntax:** How to Describe a Repeating Group With MAPFIELD

FIELD = name, ALIAS = MAPFIELD, USAGE = format, ACTUAL = format,$

where:

*name*

Is the name you choose to provide for this field.

**ALIAS**

MAPFIELD is assigned as the alias of the field that is the RECTYPE indicator.

**USAGE**

Follows the usual field format.

**ACTUAL**

Follows the usual field format.

The descendant segment values depend on the value of the MAPFIELD. They are described as separate segments, one for each possible value of MAPFIELD, and all descending from the segment that has the MAPFIELD. A special field, MAPVALUE, is described as the last field in these descendant segments after the ORDER field, if one has been used. The actual MAPFIELD value is supplied as the ALIAS of MAPVALUE.

**Syntax:** How to Use MAPFIELD for a Descendant Repeating Segment in a Repeating Group

FIELD = MAPVALUE, ALIAS = alias, USAGE = format, ACTUAL = format, ACCEPT = {list|range},$

where:

**MAPVALUE**

Indicates that the segment depends on a MAPFIELD in its parent segment.

**alias**

Is the primary MAPFIELD value, if an ACCEPT list is not specified. If there is an ACCEPT list, this can be any value.

**USAGE**

Is the same format as the MAPFIELD format in the parent segment.

**ACTUAL**

Is the same format as the MAPFIELD format in the parent segment.
list

Is the list of one or more lines of specified MAPFIELD values for records that have the same segment layout. The maximum number of characters allowed in the list is 255. Each item in the list must be separated by either a blank or the keyword OR. If the list contains embedded blanks or commas, it must be enclosed within single quotation marks ('). The list may contain a single MAPFIELD value.

For example:

```
FIELDNAME = MAPVALUE, ALIAS = A, USAGE = A1, ACTUAL = A1, ACCEPT = A OR B OR C,$
```

range

Is a range of one or more lines of MAPFIELD values for records that have the same segment layout. The maximum number of characters allowed in the range is 255. If the range contains embedded blanks or commas, it must be enclosed within single quotation marks (').

To specify a range of values, include the lowest value, the keyword TO, and the highest value, in that order.

Example: Using MAPFIELD and MAPVALUE

Using the sample data source at the beginning of this section, the Master File for this data source looks like this:

```
FILENAME=EXAMPLE,SUFFIX=FIX,$
SEGNAME=ROOT,SEGTYPE=S0,$
    FIELD =A, ,A14 ,A14 ,$
    FIELD =B, ,A10 ,A10 ,$
    FIELD =FLAG ,MAPFIELD ,A01 ,A01 ,$
SEGNAME=SEG001,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0 ,$
    FIELD =C, ,A05 ,A05 ,$
    FIELD =D, ,A07 ,A07 ,$
    FIELD =MAPVALUE ,1 ,A01 ,A01 ,$
SEGNAME=SEG002,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0 ,$
    FIELD =E, ,D12.2 ,D8 ,$
    FIELD =MAPVALUE ,2 ,A01 ,A01 ,$
```

Note: MAPFIELD can only exist on an OCCURS segment that has not been remapped. This means that the segment definition cannot contain POSITION=fieldname.

MAPFIELD and MAPVALUE may be used with SUFFIX=FIX and SUFFIX=VSAM data sources.
Establishing VSAM Data and Index Buffers

### How to: Establish VSAM Data and Index Buffers

Two SET commands make it possible to establish DATA and INDEX buffers for processing VSAM data sources online.

The AMP sub-parameters BUFND and BUFNI enable users to enhance the I/O efficiency of TABLE, TABLEF, MODIFY, and JOIN against VSAM data sources by holding frequently used VSAM Control Intervals in memory, rather than on physical DASD. By reducing the number of physical Input/Output operations, you may improve job throughput. In general, BUFND (data buffers) increase the efficiency of physical sequential reads, whereas BUFNI (index buffers) are most beneficial in JOIN or KEYED access operations.

### Syntax: How to Establish VSAM Data and Index Buffers

```plaintext
ENGINE VSAM SET BUFND {n | 8}
ENGINE VSAM SET BUFNI {n | 1}
```

Where:

- `n` is the number of data or index buffers. BUFND=8 and BUFNI=1 (eight data buffers and one index buffer) are the default values. The AMODE parameter determines whether the buffers are created above or below the line. SET AMODE=31 places the buffers above the line. SET AMODE=24 places the buffers below the line.

To determine how many buffers are in effect at any time, issue the query:

```plaintext
ENGINE VSAM SET ?
```

### Using a VSAM Alternate Index

#### Example:

Describing a VSAM Alternate Index

Using IDCAMS

VSAM key-sequenced data sources support the use of alternate key indexes (keys). A key-sequenced VSAM data source consists of two components: an index component and a data component. The data component contains the actual data records, while the index component is the key used to locate the data records in the data source. Together, these components are referred to as the base cluster.
An alternate index is a separate, additional index structure that enables you to access records in a KSDS VSAM data source based on a key other than the data source primary key. For instance, you may usually use a personnel data source sequenced by Social Security number, but occasionally need to retrieve records sorted by job description. The job description field might be described as an alternate index. An alternate index must be related to the base cluster it describes by a path, which is stored in a separate data source.

The alternate index is a VSAM structure and is, consequently, created and maintained in the VSAM environment. It can, however, be described in your Master File, so that you can take advantage of the benefits of an alternate index.

The primary benefit of these indexes is improved efficiency. You can use it as an alternate, more efficient, retrieval sequence or take advantage of its potential indirectly, with screening tests (IF...LT, IF...LE, IF...GT, IF...GE, IF...EQ, IF...FROM...TO, IF...IS), which are translated into direct reads against the alternate index. You can also join data sources with the JOIN command through this alternate index.

It is not necessary to identify the indexed view explicitly in order to take advantage of the alternate index. An alternate index is automatically used when described in the Master File.

To take advantage of a specific alternate index during a TABLE request, provide a WHERE or IF test on the alternative index field that meets the above criteria. For example:

```
TABLE FILE CUST
PRINT SSN
WHERE LNAME EQ 'SMITH'
END
```

As you see in the Master File in Describing a VSAM Alternate Index on page 2628, the LNAME field is defined as an alternate index field. The records in the data source are retrieved according to their last names, and certain IF screens on the field LNAME result in direct reads. Note that if the alternate index field name is omitted, the primary key (if there is any) is used for a sequential or a direct read, and the alternate indexes are treated as regular fields.

Alternate indexes must be described in the Master File as fields with FIELDTYPE=I. The ALIAS of the alternate index field must be the file name allocated to the corresponding path name. Alternate indexes can be described as GROUPs if they consist of portions with dissimilar formats. Remember that ALIAS=KEY must be used to describe the primary key.

Only one record type can be referred to in the request when using alternate indexes, but there is no restriction on the number of OCCURS segments.

Note that the path name in the allocation is different from both the cluster name and the alternate index name.

If you are not sure of the path names and alternate indexes associated with a given base cluster, you can use the IDCAMS utility. (See the IBM manual entitled Using VSAM Commands and Macros, for details.)
**Example: Describing a VSAM Alternate Index**

Consider the following:

FILENAME = CUST, SUFFIX = VSAM,$
SEGNAME = ROOT, SECTYPE = S0,$
   GROUP = G, ALIAS = KEY, A10, A10,$
   FIELD = SSN,   SSN, A10, A10,$
   FIELD = FNAME, DD1, A10, A10, FIELDTYPE=I,$
   FIELD = LNAME, DD2, A10, A10, FIELDTYPE=I,$

In this example, SSN is a primary key and FNAME and LNAME are alternate indexes. The path data set must be allocated to the ddname specified in ALIAS= of your alternate index field. In this Master File, ALIAS=DD1 and ALIAS=DD2 each have an allocation pointing to the path data set. FNAME and LNAME must have INDEX=I or FIELDTYPE=I coded in the Master File. CUST must be allocated to the base cluster.

**Example: Using IDCAMS**

The following example demonstrates how to use IDCAMS to find the alternate index and path names associated with a base cluster named CUST.DATA:

First, find the alternate index names (AIX) associated with the given cluster.

**IDCAMS input:**

LISTCAT CLUSTER ENTRIES(CUST.DATA) ALL

**IDCAMS output (fragments):**

CLUSTER -------- CUST.DATA
   ASSOCIATIONS
      AIX --------- CUST.INDEX1
      AIX --------- CUST.INDEX2

This gives you the names of the alternate indexes (AIX): CUST.INDEX1 and CUST.INDEX2.

Next, find the path names associated with the given AIX name:

**IDCAMS input:**

LISTCAT AIX ENTRIES (CUST.INDEX1 CUST.INDEX2) ALL

**IDCAMS output (fragments):**

AIX ---------CUST.INDEX1
   ASSOCIATIONS
      CLUSTER -- CUST.DATA
      PATH ------CUST.PATH1
      AIX ---------CUST.INDEX2
   ASSOCIATIONS
      CLUSTER -- CUST.DATA
      PATH ------CUST.PATH2

This gives you the path names: CUST.PATH1 and CUST.PATH2.
This information, along with the TSO DDNAME command, may be used to ensure the proper allocation of your alternate index.

**VSAM Record Selection Efficiencies**

**In this section:**
- Reporting From Files With Alternate Indexes

The most efficient way to retrieve selected records from a VSAM KSDS data source is by applying an IF screening test against the primary key. This results in a direct reading of the data using the data source index. Only those records that you request are retrieved from the file. The alternative method of retrieval, the sequential read, forces the adapter to retrieve all the records into storage.

Selection criteria that are based on the entire primary key, or on a subset of the primary key, cause direct reads using the index. A partial key is any contiguous part of the primary key beginning with the first byte.

IF selection tests performed against virtual fields can take advantage of these efficiencies as well, if the full or partial key is embedded in the virtual field.

The EQ and IS relations realize the greatest performance improvement over sequential reads. When testing on a partial key, equality logic is used to retrieve only the first segment instance of the screening value. To retrieve subsequent instances, NEXT logic is used.

Screening relations GE, FROM, FROM-TO, GT, EXCEEDS, IS-MORE-THAN, and NOT-FROM-TO all obtain some benefit from direct reads. The following example uses the index to find the record containing primary key value 66:

```
IF keyfield GE 66
```

It then continues to retrieve records by sequential processing, because VSAM stores records in ascending key sequence. The direct read is not attempted when the IF screening conditions NE, IS-NOT, CONTAINS, OMITS, LT, IS-LESS-THAN, LE, and NOT-FROM are used in the report request.

**Reporting From Files With Alternate Indexes**

Similar performance improvement is available for ESDS and KSDS files that use alternate indexes. An alternate index provides access to records in a key sequenced data set based on a key other than the primary key.

All benefits and limitations inherent with screening on the primary or partial key are applicable to screening on the alternate index or partial alternate index.

**Note:** It is not necessary to take an explicit indexed view to use the index.
Maintaining VSAM KSDS Data Sources

In this section:
- General Guidelines for Maintaining VSAM KSDS Data Sources
- Sample VSAM KSDS Master Files and Data Maintenance Examples

The Adapter for VSAM supports SQL update commands for VSAM KSDS data sources without the use of remote procedures. For example, UPDATE, INSERT, and DELETE will be translated into equivalent VSAM low-level read/write calls. No changes to the Master File are required in order to issue SQL INSERT, UPDATE, or DELETE commands against VSAM data sources.

General Guidelines for Maintaining VSAM KSDS Data Sources

How to:
- Issue an SQL INSERT Command in VSAM
- Issue an SQL DELETE Command in VSAM
- Issue an SQL UPDATE Command in VSAM
- Obtain the Number of Records Affected by an SQL INSERT, UPDATE, or DELETE Command

Reference:
- Processing Not Supported for Maintaining VSAM Data Sources

The Structured Query Language (SQL) is intended to be used for access to relational tables, which are flat structures. A VSAM record, like a row in a relational table, has no hierarchical or network structure. However, unlike a relational table, a VSAM record may have repeating fields. It may also have multiple record types which require a different interpretation of the record layout from one record to another.

The adapter is designed to work against a single VSAM record. When a VSAM record can have multiple record layouts, the Master File describes the VSAM record as multiple segments, one for the fixed portion of the record (the root segment) and a separate descendant segment to describe each record layout. Similarly, when a VSAM record has repeating fields, the Master File describes this portion of the VSAM record as an OCCURS segment. However, to VSAM and SQL, these multiple segments still describe one VSAM record. Only one VSAM record can be the target of the SQL Data Manipulation Language (DML) statement. SQL set orientated behavior (multiple updates with one SQL statement) is not supported.
VSAM KSDS data sources have a unique key. To identify the record that is the target of the SQL statement, the SQL statement must supply the complete key for that record.

**RECTYPEs in the Master File**

When the Master File describes descendant segments with different RECTYPE values, you can insert a record without supplying a value for the RECTYPE field as long as the adapter can identify which RECTYPE is correct for the segment to be inserted. Since each RECTYPE is defined in a different segment in the Master File, if the field list for the INSERT contains a field name specific to that segment, the adapter can identify and insert the correct RECTYPE value.

**OCCURS Segments in the Master File**

When you want to update, insert, or delete a repeating group (OCCURS segment in the Master File), the technique you use depends on whether there are a fixed or variable number of occurrences defined in the Master File:

- For a fixed number of occurrences (OCCURS=n in the Master File), you must insert the record and then update a specific occurrence of the repeating group. The most efficient way to identify the occurrence is to specify a value for the ORDER field. You can also identify the occurrence by specifying any unique field value in the occurrence. The ORDER field is an internal counter maintained by the adapter for OCCURS segments.

- For a variable number of occurrences (OCCURS=field or OCCURS=VARIABLE in the Master File), you can insert a repeating group at the same time as the fixed portion of the record. Again, you identify the specific occurrence that is the target of the SQL command by supplying the ORDER field or a unique field value.

Note that when a fixed number of occurrences is specified in the Master File, any attempt to access an occurrence number greater than that fixed number generates an error.

VSAM records can be fixed or variable length. When you add or delete a repeating group in a fixed length record, the record length stays the same. When you add or delete a repeating group in a variable length record, the record length changes.

The WHERE clause of the SQL statement must contain the complete key for the target record. Any record referenced in the SQL query must, using the WHERE clause, be a unique occurrence of that record. If additional fields are included in the WHERE clause for any record, they will be used in conjunction with the key, to identify the segment.
Syntax: **How to Issue an SQL INSERT Command in VSAM**

```
INSERT INTO mfdname [(field1, field2 ...)] VALUES (value1, value2 ...)
```

**General Rules**

The following rules apply to SQL INSERT syntax:

- If you do not specify the field name list, the value list must contain values for all fields in all segments in the Master File as long as the Master File only specifies a single path VSAM file.

- If you specify the field name list, the value list only needs to specify, in field name list order, values for the field names supplied. As a minimum, you must supply all the key fields to the target record.

- If a record is not present, default values will be generated for all non-key fields not supplied.

- To insert a repeating field described with OCCURS=n in the Master File, insert the key field first and then use SQL UPDATE to enter a value in the repeating field. In the WHERE clause of the UPDATE command, specify a value for the ORDER field (or any unique field value) to identify which occurrence to update. Occurrences must be inserted in sequential order.

Syntax: **How to Issue an SQL DELETE Command in VSAM**

```
DELETE FROM mfdname WHEREfieldname=value [AND fieldname=value ...]
```

**General Rules**

The following rules apply to SQL DELETE syntax:

- To delete a complete record, you must supply the complete key for the target record. Only one target segment will be deleted.

- To delete a repeating field, you must specify the complete key for the record and a value for the ORDER field (or any unique field value) to identify which occurrence to delete.
**Syntax:**  How to Issue an SQL UPDATE Command in VSAM

```
UPDATE mfdname  SET fieldname=value [SET fieldname=value...]  
WHERE fieldname=value  
[AND fieldname=value]
```

**General Rules**

The following rules apply to SQL UPDATE syntax:

- As a minimum, in the WHERE condition, you must supply all the key fields the record to be updated. Only one target record will be updated.
- To update a repeating field, you must specify the complete key for the record and a value for the ORDER field (or any unique field value) to identify which occurrence to update.

**Syntax:**  How to Obtain the Number of Records Affected by an SQL INSERT, UPDATE, or DELETE Command

```
PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.
```

**Tip:** You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

```
*ENGINE* INT SET PASSRECS {ON | OFF}
```

where:

**INT**

Indicates that the PASSRECS setting in this command will be applied globally to all adapters that support SQL INSERT, UPDATE, and DELETE commands.

**ON**

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

**OFF**

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

In addition, the adapter updates the &RECORDS system variable with the number of rows affected. You can access this variable using Dialogue Manager.

**Reference:**  Processing Not Supported for Maintaining VSAM Data Sources

The following processing is not supported:
null data values.

- Embedded SELECT within INSERT.
- Cursor control, for example, WHERE CURRENT OF on UPDATE or DELETE processing.

Sample VSAM KSDS Master Files and Data Maintenance Examples

**Example:**

- Inserting a VSAM KSDS Record With OCCURS=n
- Deleting an Occurrence of a Repeating Field in a VSAM KSDS Record
- Deleting a VSAM KSDS Record
- Inserting a VSAM KSDS Record With OCCURS=field
- Inserting a Record in a VSAM KSDS Record With Record Types
- Updating an Occurrence of a Repeating Group in a VSAM KSDS Record Record Types
- Deleting an Occurrence of a Repeating Group in a VSAM KSDS Record With RecordTypes
- Inserting a Record in a VSAM KSDS Record With a MAPFIELD
- Updating an Occurrence of a Repeating Field in a VSAM KSDS Record With a MAPFIELD
- Deleting an Occurrence of a Repeating Field in a VSAM KSDS Record With a MAPFIELD

The following examples show how to insert, update, and delete records and occurrences of repeating groups in a VSAM KSDS data source.
**Example:** Inserting a VSAM KSDS Record With OCCURS=n

Consider the following Master File that describes a repeating field (FLD005 in segment R010) with OCCURS=3. Note that the Master File also describes the ORDER field, which is an internal counter for OCCURS segments:

```plaintext
FILE=VSMW0200 , SUFFIX=VSAM, $
DATASET='EDAQA.VSMW0200.CLUSTER', $ 
SEGNAME=ROOT , SEGTYPE=S0, $
GROUP=GRPKEYA , ALIAS=KEY , A8 , A8 , $ 
FIELDNAME = FLD000 , , A8 , A8 , $ 
FIELDNAME = FLD001 , , A2 , A2 , $ 
FIELDNAME = FLD003 , , A4 , A4 , $ 
FIELDNAME = ACCOUNT , , A2 , A2 , $ 
SEGNAME=R010 , SEGTYPE=S0, PARENT=ROOT, OCCURS=3 , $ 
FIELDNAME = FLD005 , , A8 , A8 , $ 
FIELDNAME = ORDER , ORDER , I4 , I4 , $ 
```

The following SQL INSERT statement inserts a record with a key field of 1245678. An OCCURS segment cannot be inserted using SQL INSERT when the number of occurrences is fixed:

```sql
SQL
INSERT INTO VSMW0200 (FLD000)
VALUES ('12345678');
END
```

The following SQL UPDATE statements place values in the occurrences of FLD005. The WHERE predicate in each SQL UPDATE command specifies the complete key for the record and a value for the ORDER field to identify which occurrence to update:

```sql
SQL
UPDATE VSMW0200
SET FLD005 = '00001001'
WHERE FLD000 = '12345678' AND ORDER = 1;
END
SQL
UPDATE VSMW0200
SET FLD005 = '00002002'
WHERE FLD000 = '12345678' AND ORDER = 2;
END
SQL
UPDATE VSMW0200
SET FLD005 = '00003003'
WHERE FLD000 = '12345678' AND ORDER = 3;
END
```

With OCCURS=n, the occurrence number referenced in the SQL statement must be less than or equal to n. If you reference an occurrence with a number greater than n, the occurrence is not updated and an error message is returned.
Example: Deleting an Occurrence of a Repeating Field in a VSAM KSDS Record

The following SQL DELETE statement deletes the first occurrence of the repeating field FLD005. The WHERE predicate identifies the complete key (FLD000='12345678') and the specific occurrence to delete (ORDER=1):

```
SQL
DELETE FROM VSMW0200
WHERE FLD000='12345678' AND ORDER=1;
END
```

Example: Deleting a VSAM KSDS Record

The following SQL DELETE statement deletes VSAM KSDS record whose key value is '12345678':

```
SQL
DELETE FROM VSMW0200 WHERE FLD000='12345678';
END
```

Example: Inserting a VSAM KSDS Record With OCCURS=field

When a repeating field has a variable number of occurrences (OCCURS=field or OCCURS=VARIABLE), you can use an SQL INSERT statement to add a new record and insert data into a specific occurrence of the repeating field.

Consider the following Master File in which the number of occurrences of FLD005 is specified by the value in the ACCOUNT field:

```
FILE=VSMW0201 ,SUFFIX=VSAM,$
DATASET='EDAQA.VSMW0200.CLUSTER', $
SEGNAME=ROOT ,SEGTYPE=S0,$
GROUP=GRPKEYA ,ALIAS=KEY ,A8 ,A8 ,$ 
FIELDNAME =FLD000 , ,A8 ,A8 ,$
FIELDNAME =FLD001 , ,A2 ,A2 ,$
FIELDNAME =FLD003 , ,A4 ,A4 ,$
FIELDNAME =ACCOUNT , ,I2 ,I2 ,$
SEGNAME=R010 ,SEGTYPE=S0, PARENT=ROOT, OCCURS=ACCOUNT ,$
FIELDNAME =FLD005 , ,A8 ,A8 ,$
FIELDNAME =ORDER ,ORDER ,I4 ,I4 ,$
```
The following SQL INSERT statement inserts a new record with key FLD000='12345678' and the value '00001001' in the first occurrence of FLD005. The ORDER field identifies the occurrence that is inserted, but it represents an internal counter and does not exist in the VSAM record:

```
SQL
INSERT INTO VSMW0201 (FLD000,FLD005,ORDER)
VALUES('12345678','00001001',1) ;
END
```

To add a second occurrence of FLD005, issue an SQL INSERT statement for key FLD000='12345678' and the value 2 for the ORDER field. Note that the occurrences must be added in order:

```
SQL
INSERT INTO VSMW0201 (FLD000,FLD005,ORDER)
VALUES('12345678','00002002',2) ;
END
```

If you attempt to add an occurrence that would make the record length exceed the maximum record length defined for the VSAM data source, the occurrence is not added and an error message is returned.

**Example: Inserting a Record in a VSAM KSDS Record With Record Types**

Consider the following Master File that describes two OCCURS segments with a variable number of occurrences. The key field is FLD000, which is followed by FLD001. Next comes any combination of the two possible layouts for the variable portion of the record. Each repeating group starts with a value that indicates the type of layout that follows. If the RECTYPE field contains the value 2, the repeating group is an instance of segment SEG002, and it contains one 8-byte field (FLD002). If the RECTYPE field contains the value 3, the repeating group is an instance of segment SEG003, and it contains two 8-byte fields (FLD003 and FLD004):

```
FILE=VSMW0208,          SUFFIX=VSAM,$
DATASET='EDAQA.VSMW0200.CLUSTER',   $
SEGNAME=ROOT,SEGTYPE=S0,$
    GROUP =GRPKEY     ,ALIAS=KEY   ,USAGE=A8,ACTUAL=A8,$
    FIELD =FLD000     ,E00         ,A08     ,A08      ,$
    FIELD =FLD001     ,E01         ,A02     ,A02      ,$
SEGNAME=SEG002,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0,$
    FIELD =RECTYPE    ,2           ,A01     ,A01      ,$
    FIELD =FLD002     ,E02         ,A08     ,A08      ,$
SEGNAME=SEG003,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0,$
    FIELD =RECTYPE    ,3           ,A01     ,A01      ,$
    FIELD =FLD003     ,E03         ,A08     ,A08      ,$
    FIELD =FLD004     ,E04         ,A08     ,A08      ,$
```
The following SQL INSERT statement adds an occurrence of SEG002. The INSERT statement references FLD002, which identifies the INSERT as an instance of SEG002. The adapter automatically inserts the value 2 in the RECTYPE field, even though it is not specified as part of the insert statement:

```sql
INSERT INTO VSMW0208 (FLD000,FLD002)
VALUES('12345678','ANTIGUA') ;
END
```

The following SQL INSERT statement adds an occurrence of SEG003. The INSERT statement references fields FLD003 and FLD004, which identifies the INSERT as an instance of SEG003. The adapter automatically inserts the value 3 in the RECTYPE field, even though it is not specified as part of the insert statement:

```sql
INSERT INTO VSMW0208 (FLD000,FLD003,FLD004)
VALUES('12345678','BRAZIL','AMERICA') ;
END
```

**Example: Updating an Occurrence of a Repeating Group in a VSAM KSDS Record**

The following SQL UPDATE statement updates an occurrence of FLD004 in the record with key '12345678'. The ORDER field is not defined in this Master File. The specific occurrence of FLD004 to update is identified by specifying a unique value of FLD003:

```sql
UPDATE VSMW0208
SET FLD004='S AMER'
WHERE FLD000='12345678' AND FLD003='BRAZIL';
END
```

**Example: Deleting an Occurrence of a Repeating Group in a VSAM KSDS Record**

The following SQL DELETE statement deletes an occurrence of FLD002 in the record with key '12345678'. The ORDER field is not defined in this Master File. The specific occurrence of FLD002 to delete is identified by specifying its unique value ('ANTIGUA'):

```sql
DELETE FROM VSMW0208
WHERE FLD000='12345678' AND FLD002='ANTIGUA';
END
```
**Example:** Inserting a Record in a VSAM KSDS Record With a MAPFIELD

Consider the following Master File that describes two OCCURS segments with a variable number of occurrences. The key field is a concatenation of fields FLD000 and FLAG (the MAPFIELD). If the FLAG field contains the value 2, the remainder of the record contains a variable number of occurrences of segment SEG002, which consists of one 8-byte field (FLD002). If the flag field contains the value 3, the remainder of the record consists of a variable number of occurrences of segment SEG003, which consists of two 8-byte fields (FLD003 and FLD004):

```
FILE=VSMW0209,          SUFFIX=VSAM,$
DATASET='EDAQA.VSMW0200.CLUSTER',   $
SEGNAME=ROOT,SEGTYPE=S0,$
   GROUP =GRPKEY ,ALIAS=KEY ,USAGE=A8,ACTUAL=A8,$
   FIELD=FLD000 ,E00 ,A07 ,A07 ,$
   FIELD=FLAG ,MAPFIELD ,A01 ,A01 ,$
SEGNAME=SEG002,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0,$
   FIELD =FLD002 ,E02 ,A08 ,A08 ,$
   FIELD =MAPVALUE ,2 ,A01 ,A01 ,$
SEGNAME=SEG003,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0,$
   FIELD =FLD003 ,E03 ,A08 ,A08 ,$
   FIELD =FLD004 ,E04 ,A08 ,A08 ,$
   FIELD =MAPVALUE ,3 ,A01 ,A01 ,$
```

The following SQL INSERT statement adds an occurrence of SEG002. The INSERT statement must provide a value for the FLAG field because it is part of the key:

```
SQL
INSERT INTO VSMW0209 (FLD000,FLAG,FLD002)
VALUES ('1234567','2','ANTIGUA') ;
END
```

The following SQL INSERT statement adds an occurrence of SEG003:

```
SQL
INSERT INTO VSMW0209 (FLD000,FLAG,FLD003,FLD004)
VALUES ('1234567','3','BRAZIL','AMERICA') ;
END
```
**Example:** Updating an Occurrence of a Repeating Field in a VSAM KSDS Record With a MAPFIELD

The following SQL UPDATE statement updates an occurrence of FLD004 in the record with key '12345673'. The ORDER field is not defined in this Master File. The specific occurrence of FLD004 to update is identified by specifying a unique value of FLD003:

```sql
SQL
UPDATE VSMW0209
SET FLD004='S AMER'
WHERE GRPKEY='12345673' AND FLD003='BRAZIL';
END
```

**Example:** Deleting an Occurrence of a Repeating Field in a VSAM KSDS Record With a MAPFIELD

The following SQL DELETE statement deletes an occurrence of FLD002 in the record with key '12345672'. The ORDER field is not defined in this Master File. The specific occurrence of FLD002 to delete is identified by specifying its unique value ('ANTIGUA'):

```sql
SQL
DELETE FROM VSMW0209
WHERE GRPKEY='12345672' AND FLD002='ANTIGUA';
END
```

**Using VSAM Relative Record Data Set (RRDS) Files**

**How to:**

Specify a Relative Record Number Field in a Master File

**Example:**

Applying Unique Keys With Records in RRDS Files

The Adapter for VSAM supports both direct and sequential retrieval of fixed- and variable-length records from RRDS files, as well as modification of those records. RRDS files are VSAM files that are accessed through Relative Record Number keys (RRNs) and are processed in basically the same manner as key-sequenced (KSDS or KSEQ) VSAM files.

The RRN field that serves as the primary (unique) key for the segment follows all real fields in the physical root segment of the Master File and establishes the sequence for the records. The RRN field description must contain the following attributes:

```
ALIAS=RRN, USAGE=I10, ACTUAL=I4
```

Records in RRDS files are processed sequentially if the request does not provide a screening condition or join for the RRN-associated field.
Syntax: How to Specify a Relative Record Number Field in a Master File

```
FILE=RRDSVSAM, SUFFIX=VSAM, DATASET=PGMYAN.RRDSVSAM.CLUSTER, $
SEGNAME=ROOT, SEGTYPE=S0, $
FIELD=CODE, USAGE=A2, ACTUAL=A2, $
FIELD=NAME, USAGE=A10, ACTUAL=A10, $
FIELD=VALUE, USAGE=P2, ACTUAL=Z1, $
FIELD=ACCESS_KEY, ALIAS=RRN, USAGE=I10, ACTUAL=I4, $
```

Example: Applying Unique Keys With Records in RRDS Files

The following examples show how to view and apply unique Relative Record Number (RRN) key values when working with records in RRDS files.

**Printing the records with their key values**

```
TABLE FILE RRDSVSAM
PRINT CODE NAME VALUE ACCESS_KEY
END
```

**Screening records by unique key values**

```
TABLE FILE RRDSVSAM
PRINT CODE NAME VALUE ACCESS_KEY
IF ACCESS_KEY GE 5
IF ACCESS_KEY LE 15
END
```

**Retrieving records by unique key values**

```
TABLE FILE RRDSVSAM
PRINT CODE NAME VALUE ACCESS_KEY
IF ACCESS_KEY EQ 5 OR 7 OR 9
END
```

**Modifying records by unique key values**

```
MODIFY FILE RRDSVSAM ECHO
FREEFORM ACCESS_KEY
MATCH ACCESS_KEY
ON NOMATCH COMPUTE CODE = 'A1';
ON NOMATCH COMPUTE NAME = 'RECORD 20';
ON NOMATCH INCLUDE
ON MATCH REJECT
DATA
ACCESS_KEY=20
END
```
Updating matching records in RRDS files by unique key values

MODIFY FILE RRDSVSAM ECHO
FREEFORM ACCESS_KEY
MATCH ACCESS_KEY
ON NOMATCH REJECT
ON MATCH
TYPE "CODE: <D.CODE>, NAME: <D.NAME>, VALUE: <D.VALUE>";
ON MATCH COMPUTE VALUE = 9;
ON MATCH UPDATE VALUE
DATA
ACCESS_KEY=20
END

Deleting RRDS records based on unique key values

MODIFY FILE RRDSVSAM ECHO
FREEFORM ACCESS_KEY
MATCH ACCESS_KEY
ON NOMATCH REJECT
ON MATCH
TYPE "CODE: <D.CODE>, NAME: <D.NAME>, VALUE: <D.VALUE>";
ON MATCH DELETE
DATA
ACCESS_KEY=7
END

Reviewing SQL Updates to VSAM Data Sources

**How to:**
Count Records Updated, Inserted or Deleted

**Reference:**
Obtain Counts of Rows Updated or Deleted

The Adapter for VSAM supports SQL INSERT, UPDATE, and DELETE operations against VSAM data sources for use in accessing and maintaining legacy systems. This facilitates development and implementation of new applications based on VSAM data sources.

**Reference:** Obtain Counts of Rows Updated or Deleted

While processing SQL transactions, you can issue the PASSRECS command to obtain counts of rows affected by each successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.
**Syntax:**  
How to Count Records Updated, Inserted or Deleted

```plaintext
*ENGINE* INT SET PASSRECS {ON|OFF}
```

where:

**INT**

Indicates that the PASSRECS setting in this command will be applied globally to all adapters that support SQL INSERT, UPDATE, and DELETE commands.

**ON**

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

**OFF**

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

In addition, the adapter updates the &RECORDS system variable with the number of rows affected. You can access this variable using Dialogue Manager.
Reviewing SQL Updates to VSAM Data Sources
The Adapter for WAND® can be used for sentiment analysis of textual data. Sentiment analysis identifies positive or negative sentiment within a document or web page. The adapter uses Wand Taxonomy, the industry-leading multi-lingual vocabulary for precision search, which provides analysis of structured data.

Sentiment analysis returns a rating between -1 and 1. A rating below zero represents a negative sentiment, while a rating above zero represents a positive sentiment.

**Topics:**
- Configuring the Adapter for WAND
- Creating Synonyms With the Adapter for WAND
Configuring the Adapter for WAND

How to:
Declare Connection Attributes

Reference:
Connection Attributes for the Adapter for WAND

Configuring the adapter consists of specifying connection information and if necessary, authentication information for at least one connection.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   or
   From the Data Management Console, expand the Adapters folder.
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for the Adapter for WAND

The Adapter for WAND is under the Social Media group folder.

Connect parameters

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.
WAND Services End-Point

Is the URL used to connect to the WAND Web Service. For example, http://wand.ibi.com:4701/soap/scorer.

Advanced HTTP connection options

Select profile

Is the profile where the connection will be stored. The default value is edaprof.

Creating Synonyms With the Adapter for WAND

How to:

Create a Synonym

After adding a WAND connection, a set of predefined synonyms and example procedures (FOCEXECs) can be created for this connection.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Adapters.
   The Adapters page opens.

2. Open the WAND folder.

3. Right-click a connection and select Create Synonym from the drop-down menu.
The Select candidate(s) for WAND Synonym(s) page opens, as shown in the following image.

4. Enter a folder name in the Application field or click the selector button (...) and navigate to one.
5. Click Create Synonym.
The synonyms and sample procedures are created in the application folder, as shown in the following image.

![Image of folder structure with synonyms and sample procedures]

**Note:**

- The metadata (Master Files and Access Files) is created in the parent folder.
- The Create Synonym process also loads a number of sample reports into the `wandsampl` subfolder that can be run out-of-the-box. These reports use sample text that is loaded during the Create Synonym process.
Creating Synonyms With the Adapter for WAND
Using the Adapter for Web Services

The Adapter for Web Services allows client applications to access Web Services providers. The adapter converts:

- Internal data manipulation language (DML) requests or SQL requests into Web Services requests.
- Web Services responses into answer sets.

Topics:

- Configuring the Adapter for Web Services
- Managing Web Services Metadata
- Capturing a SOAP Request Using FILEDEF SOAPTSCQ in a Procedure
Configuring the Adapter for Web Services

In this section:
Declaring Connection Attributes
Security for Web Services

Configuring the adapter consists of specifying connection and authentication information for at least one connection.

Declaring Connection Attributes

How to:
Declare Connection Attributes
Declare Connection Attributes Manually

Example:
Declaring Connection Attributes

Reference:
Connection Attributes for Web Services

In order to access the Web Services provider hosting the target Web service, the adapter requires connection information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (user.prf), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (user.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one Web Services provider by including multiple SET CONNECTION_ATTRIBUTES commands.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
From the Data Management Console, expand the Adapters folder. The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure. The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for Web Services

The Web Services adapter is under the Procedures group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the Configure button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

WSDL URL

URL of the WSDL that describes the Web service. Addresses can begin with:

file://
http://
https://

This value is required for creating a synonym only; otherwise, it is ignored.

PROXY Server IP Address

IP address of the proxy server, which intercepts requests and forwards them to the real server.

PROXY Port

Port number on which the proxy server listens. The default port number is 80.
Certificate

Location of locally-stored user-provided server x.509 certificates for SSL authentication. The certificate file is used to authenticate the server to which the adapter is connecting.

For trusted, the trusted certificate file (trustedcertfile) points to a file of CA certificates in PEM format, as illustrated below:

```
-----BEGIN CERTIFICATE-----
... (CA certificate in base64 encoding) ...
-----END CERTIFICATE-----
```

A trusted certificate file can contain several CA certificates. You can add text before, between, and after certificates. For example, to provide descriptions of certificates.

For non-trusted, the next three fields are added to the configuration pane.

Key file

Is the private key used for creating the client X.509 certificate in PEM format. This option is used together with a certificate for a non-trusted connection.

Pass phrase

Is the password used to unlock the key file. The value is needed only if the key file is encrypted.

Label

Identifies a certificate in the file if the file contains more than one certificate.

Security

There are two methods by which a user can be authenticated when connecting to a Web Services provider:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to Web Services, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to Web Services, at connection time, for authentication.

User

Primary authorization ID by which you are known to Web Services.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.
If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

**Via MFD/Select Application**

This option is used only for chained authentication. For details about this process, see *How to Configure the Adapter for Chained Execution* on page 2658.

**End Points**

This option appears on a second configuration pane, after you click the Next button.

Select the End Points URL for the Web Services provider from the drop-down list.

**Syntax:**

*How to Declare Connection Attributes Manually*

The user ID and password are explicitly specified for each connection and passed to Web Services, at connection time, for authentication. The syntax is

```plaintext
ENGINE SOAP SET CONNECTION_ATTRIBUTES connection/
 [user[,pswd]]:'endpoint_URL WSDL_URL [AUTH:applid/mf] [fieldname="value"
 ...]
 [PROXY:proxy_IP_address] [PROXY:P:[80|port_number]]
 [CERTIFICATE:cert_location [cert_key=key_file][cert_phrase=pass_phrase]
 [cert_label= cert_label]]'
```

where:

**SOAP**

Indicates the adapter.

**connection**

Is the logical name used to identify this particular set of attributes.

**user, pswd**

If specified, the user ID and password are passed to the authentication operation defined in the AUTH parameter at connection time.

For chained authentication, these are required fields if defined in the authentication Master File, either in the header or in the groups description. For related information, see *How to Configure the Adapter for Chained Execution* on page 2658.

**endpoint_URL**

Is the URL of the Web Services provider.
**WSDL_URL**

Is the URL of the WSDL that describes the Web service. This is used to create a synonym.

**applid/mf**

For chained authentication, this is the location on the server of the Master File that describes the associated authentication operation. For related information, see *How to Configure the Adapter for Chained Execution* on page 2658.

**fieldname= value**

For chained authentication in which you are passing additional parameters to an authentication operation, *fieldname* corresponds to the field defined with NEED_VALUE value in the ACCESS_PROPERTY parameter in the Master File, except for fields using the reserved names USERNAME and PASSWORD.

For an illustration, see *Passing Additional Parameters to an Authentication Operation* on page 2661.

**Note:**

- Values provided in the SET CONNECTION_ATTRIBUTES command overwrite default values set in XDEFAULT parameter in the Master File.

- Field values must be enclosed in double quotation marks (") and cannot contain double or single quotation marks.

**proxys_IP_address**

Is the IP address of the proxy server, which intercepts requests and forwards them to the real server.

**port_number**

Is the port number on which the proxy server listens. The default port number is 80.

**cert_location**

Is the location of locally-stored user-provided server x.509 certificates (Trusted CA) for SSL authentication. The certificate file is used to authenticate the server to which the adapter is connecting.

The trusted certificate file (*trustedcertfile*) points to a file of CA certificates in PEM format, as illustrated below:

```
-----BEGIN CERTIFICATE-----
...
(CA certificate in base64 encoding) ...
-----END CERTIFICATE-----
```

A trusted certificate file can contain several CA certificates. You can add text before, between, and after certificates. For example, to provide descriptions of certificates.
If you wish to specify a Non-trusted certificate, enter the following additional information:

```
[cert_key=key_file] [cert_phrase=pass_phrase] [cert_label=cert_label]
```

**key_file**
Is the private key used for creating the client X.509 certificate in PEM format. This entry is required for a non-trusted connection.

**pass_phrase**
Is the password used to unlock the key file. This entry is needed only if the key file is encrypted.

**cert_label**
Identifies a certificate in the file if the file contains more than one certificate.

**Example:** Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command allow the application to access the Web application named SAMPLEAPP.

```
ENGINE SOAP SET CONNECTION_ATTRIBUTES esriR/45678,4456789DFAFC: 'http://arcweb.esri.com/services/v2/AddressFinder file://D:\users\WSDL\ESRI\AddressFinder.wsdl AUTH:ESRI/gettoken'
```

**Security for Web Services**

**How to:**
Configure the Adapter for Chained Execution

**Example:**
Configuring Chained Authentication
Passing Additional Parameters to an Authentication Operation

Chained execution of an authentication operation is used when the web server returns a response containing a cookie or a token, to be used in the subsequent processing operation. Chained execution is defined in the connection string associated with the requested operation. When a cookie is used, both connection strings (authentication and execution) must contain the same end point URL.

The Adapter for Web Services supports the following security facilities:
Cookies, containing user credentials, which are in effect for the length of a TSCOM agent session (that is, between user connect and user disconnect). The scope of the cookie is the single TSCOM agent. The received cookie is sent back to the sender's IP, along with subsequent SOAP requests.

Identification token values, which are returned by an authentication operation and are acceptable to associated execution operations.

Chained authentication supports the explicit and passthru (with PING capabilities) security models.

To use chained authentication you must declare the connection for authentication, then create a Master File that contains the authentication specifications (using an authentication string) and store it in an application. You can then use the authentication metadata to create one or more associated execution connection strings. For details, see How to Configure the Adapter for Chained Execution on page 2658.

Note that when the connection string contains user ID and password information and chained authentication is not defined, basic HTTP authentication is used. That is, the user ID and password are encrypted using the x64 algorithm and then used to establish the HTTP connection.

Procedure: How to Configure the Adapter for Chained Execution

Follow these steps to configure the adapter for chained authentication:

1. Create a connection string using a WSDL URL that describes authentication operations. This connection is needed to specify the authentication end-point URL.

   To complete this step, in the Web Console or the Data Management Console Connection Parameters pane, type the WSDL URL, click Next, and select an End Points URL from the drop-down list.

   Keep in mind that if a cookie (rather than a token) is to be used in the subsequent processing operation, you must specify the same end point URL for this authentication connection string and for the execution connection string that you specify in step 3.

2. Create synonyms for relevant authentication operations.

   To complete this step, from the Web Console or the Data Management Console, create the synonym, then open the graphical Synonym Editor to edit the synonym using the following guidelines.

   Authentication synonyms must include the following input fields:

   USERNAME

   The user ID value is taken from the connection string defining the operation to be executed.
The password value is taken from the connection string defining the operation to be executed.

Authentication synonyms may also include fields with the following access properties. The following fields must belong to segments describing the SOAP request:

**ACCESS_PROPERTY=NEED_VALUE**

Defines fields that provide additional parameters for an authentication operation. You can supply default values in XDEFAULT parameters. Values provided in the associated connection string overwrite the default values.

There may be more than one such field.

The following fields must belong to segments describing the SOAP response:

**ACCESS_PROPERTY=AUTHRESP**

Defines fields that describe the result of an authentication operation. Correct response values must be provided in the ACCEPT attribute (using the OR predicate if more than one value is acceptable).

There may be more than one such field. The operation is considered invalid if at least one of the fields contains a non-acceptable value.

**ACCESS_PROPERTY=AUTHTOKEN**

Defines a field that contains a response token to be passed as an input value to the operation to be executed. There can be only one such field. If none is defined, the authentication operation is expected to return a cookie.

3. Create a connection string using a WSDL URL that describes the operation and the end point of the execution request, and a previously created authentication operation synonym.

To complete this step, from the Web Console or the Data Management Console Connection Parameters pane, type the WSDL URL, then from the Via MFD/Select Applications drop-down list, select the location on the server of the Master File that describes the associated authentication operation. Click Next and select the End Points URL from the drop-down list.

4. Create synonyms for relevant execution operations.

From the Web Console or the Data Management Console, create the synonym.

5. Ensure that the operation synonyms have an input field that describes the authenticating token (if needed) using ACCESS_PROPERTY=AUTHTOKEN.

To complete this step, from the Web Console or the Data Management Console, open the graphical Synonym Editor to edit the synonym as described.
Example: Configuring Chained Authentication

**Connection strings:**

```xml
ENGINE SOAP SET CONNECTION_ATTRIBUTES esriA/,: 'https://arcweb.esri.com/services/v2/Authentication file:///D:\users\WSDL\ESRI\Authentication.wsd1'

ENGINE SOAP SET CONNECTION_ATTRIBUTES esriR/109618,8366C1649D9DFAFC: 'http://arcweb.esri.com/services/v2/AddressFinder file:///D:\users\WSDL\ESRI\AddressFinder.wsdl AUTH:ESRI/gettoken'
```

**Master File fragment describing an authentication operation:**

```xml
FILENAME=GETTOKEN, SUFFIX=SOAP , $ SEGMENT=GETTOKEN, SEGTYPE=S0, $ FIELDNAME=USERNAME, ALIAS=username, USAGE=A30, ACTUAL=A30, ACCESS_PROPERTY=(NEED_VALUE), $ FIELDNAME=PASSWORD, ALIAS=password, USAGE=A30, ACTUAL=A30, ACCESS_PROPERTY=(NEED_VALUE), $ FIELDNAME=__RESPONSE, USAGE=TX80L, ACTUAL=TX, ACCESS_PROPERTY=(INTERNAL), $ SEGMENT=RESPONSE, SEGTYPE=S0, SEGSUF=XML , PARENT=GETTOKEN, POSITION=__RESPONSE, $ FIELDNAME=RESPONSE, ALIAS=getToken0Out, USAGE=A1, ACTUAL=A1, ACCESS_PROPERTY=(INTERNAL), $ FIELDNAME=RESULT, ALIAS=Result, USAGE=A120, ACTUAL=A120, ACCESS_PROPERTY=(AUTHTOKEN), REFERENCE=RESPONSE, PROPERTY=ELEMENT, $
```
 mastering File fragment describing a data retrieval operation:

FILENAME=FINDADDRESS, SUFFIX=SOAP, $
SEGMENT=FINDADDRESS, SEGTYPE=S0, $
GROUP=ADDRESS, ALIAS=address, USAGE=A210, ACTUAL=A210, $
FIELDNAME=HOUSENUMBER, ALIAS=houseNumber, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), XDEFAULT='2815', $
FIELDNAME=STREET, ALIAS=street, USAGE=A30, ACTUAL=A30,

2662 WebFOCUS
Managing Web Services Metadata

In this section:
- Creating Synonyms
- Using Static Joins
- What Is a WSDL File?
- Mapping Attributes and Default Values
- Using Arrays as Input Values
- Using Arrays as Input Values for XML Elements and Their Attributes
- Modifying Namespace Qualifiers in WSDL Schemas
- Data Type Support
- Date-Time Processing

When the server accesses a Web Services provider, it needs to know how to pass parameters to and accept responses from the Web service operation. For each operation the server will access, you create a synonym that describes the operation and the server mapping, which is provided through the WSDL file for the Web Service.

Creating Synonyms

How to:
Create a Synonym

Reference:
- Synonym Creation Parameters for Web Services
- Managing Synonyms
- Master File Attributes
- Access File Attributes

A synonym defines a unique logical name (also known as an alias) for each Web Services operation. Synonyms are useful because:

- They insulate client applications from changes to the location and identity of a request. You can move or rename a request without modifying the client applications that use it. You need make only one change, redefining the request synonym on the server.
- They provide support for the extended metadata features of the server, such as virtual fields and security mechanisms.

Creating a synonym generates a Master File and an Access File. These are metadata that describe the Web Services request to the server.

Each synonym you create represents a single operation.

**Note:** Each synonym describes the Web Services operations of a particular provider. If the operation parameters are changed, the synonym must be recreated.

**Procedure:** **How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click **Applications**.
   
The Applications page opens.

2. Click the **New** button and select **Synonym** from the drop-down menu.
   
The **Select adapter to configure or Select connection to create synonym** pane opens.

3. Click a connection for the configured adapter.
   
The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click **Create Synonym**.
   
The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

**Note:**

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting **Create Synonym**.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see **Validation for Special Characters and Reserved Words** on page 2821.
Reference: Synonym Creation Parameters for Web Services

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

Filter Operations by Name

Leave this check box blank if you do not wish to filter the operations for which to create synonyms.

Select the check box to filter the operations. You are prompted an operation name. Enter a string for filtering the operations, inserting the wildcard character (%) as needed at the beginning and/or end of the string.

For example, enter: ABC% to select all operations whose names begin with the letters ABC; %ABC to select operations whose names end with the letters ABC; %ABC% to select operations whose names contain the letters ABC at the beginning, middle, or end.

Select Operations button

Click this button to select all or filtered operations.

Validate

Select the Validate check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See Validation for Special Characters and Reserved Words on page 2821 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-' '; ' ' "; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the Make unique check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Strict SOAP data type

By default, a SOAP request generated from a table request omits all elements tags for which screening values are not provided. If this is the behavior you want, leave the Strict SOAP data type box unchecked.

If you wish to pass empty element tags as well as those that contain values, click the Strict SOAP data type check box.
This option applies to both the body and header in a SOAP request.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the **Overwrite existing synonyms** check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.

**Default Synonym Name**

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

**To create synonyms**

- **For all operations in the list**, select the check box to the left of the Default Synonym Name column.
- **For specific operations**, select the corresponding check boxes.

**Reference:** Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| **Edit as Text** | Enables you to view and manually edit the Master File synonym.  
**Note:** To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File. |
| **Edit Access File as Text** | Enables you to view and manually edit the Access File synonym.  
**Note:** This option is available only when an Access File is created as part of the synonym. |
| **Sample Data** | Retrieves up to 20 rows from the associated data source. |
| **Data Profiling** | Data Profiling provides the data characteristics for synonym columns.  
Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.  
Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls. |
| **Refresh Synonym (if applicable)** | Regenerates the synonym. Use this option if the underlying object has been altered. |
| **Data Management** | Followed by these options, if applicable:  
**Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.)  
**Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted.  
**Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values.  
**Reorganize.** Recreates the data source table preserving original data.  
**Note:** This option is not available in the Web Console. |
Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the Server Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS manual for details about Impact Analysis reports.

Copy
Copies the synonym to the clipboard.

Delete
Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.

Cut
Deletes the synonym and places it on the clipboard.

Properties
Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

Reference: Master File Attributes

<table>
<thead>
<tr>

Using Static Joins

**Example:**
Adding a Static Join From the Data Management Console Synonym Editor

**Reference:**
Join Options

You can describe various views of the same physical XML document using Master Files and Access Files.

- In the Master File, you use REFERENCE attributes in field definitions to reflect physical relationships between tags in XML document hierarchies and PARENT attributes, which establish logical hierarchical relationships.

- In the Access File, you use the KEYFLD and IXFLD attributes to identify the XML tags that act as primary/foreign keys in the XML document hierarchies, which establish the logical join relationships. The parent field (foreign key) defined in KEYFLD supplies the value for cross-referencing; the descendant field (primary key) defined in IXFLD contains the corresponding value.

The adapter implements join matching values at run time.

You can use static Joins to create join relationships between hierarchically unrelated integral schema ComplexType definitions using any combination of data nodes.

Any XML tags belonging to these definitions can be used to create join pairs. In addition, you can multiply instances of the same physical segment to reflect logical join relationships as needed.

Using a Join can also provide a way to produce multiple executions of a Web service. However, the user cannot change the properties of the fields that describe the Web service input message. The original WSDL controls the acceptable data types for both the input and output. The Join must be to fields belonging to the root segment, and the ACCESSPROPERTY parameter must be set to NEED_VALUE. The Join must also be unique to avoid looping.

**Note:** Static (embedded) Joins are not directly supported by the Create Synonym facility. To take advantage of this feature, after a synonym is generated you must modify its Master and Access Files. The Data Management Console Synonym Editor is the recommended tool for such modifications since it provides an easily identifiable segments hierarchy with drag and drop capability and a visual calculator for KEYFLD/IXFLD modifications. Using the DMC, you can quickly add all duplicate segments to the Master File, then delete any unneeded segments.
In some cases, schemas (such as those produced by Microsoft tools and reflecting relationships between the original MS SQL Server database tables) contain proper XML constraints (unique/key/keyref) for describing joins. You can use this information to modify the Master File:

- The elements `unique` and `key` define the primary key for the element (segment).
- The element `keyref` defines the foreign key for the element (segment).

For an example of how to use the Data Management Console to modify the Master File, see *Adding a Static Join From the Data Management Console Synonym Editor* on page 2671.

**Example:** Adding a Static Join From the Data Management Console Synonym Editor

This example displays a fragment of the WSDL code from which a synonym called GetAllEmployees will be generated.

The schema shows a Constraint relationship between the Employee segment, keyed on the EID field, and the Employee Relative segment, keyed on ERID field.

```xml
<xs:unique msdata:PrimaryKey="true" name="Constraint1">
  <xs:selector xpath="./Employee" />
  <xs:field xpath="EId" />
</xs:unique>

<xs:unique msdata:ConstraintName="Constraint1" msdata:PrimaryKey="true"
  name="EmployeeRelative_Constraint1">
  <xs:selector xpath="./EmployeeRelative" />
  <xs:field xpath="ErId" />
</xs:unique>

<xs:keyref msdata:ConstraintOnly="true"
  name="EmployeeRelative_Employee_EId_EId"
  refer="mstns:Constraint1">
  <xs:selector xpath="./EmployeeRelative" />
  <xs:field xpath="EId" />
</xs:keyref>
```

Working in the Data Management Console, you can quickly establish a Join relationship between the Employee and EmployeeRelative Segments in the synonym in order to be able to report against both segments at the same time.

1. Open the DMC and open the Application Directory folder where the synonym is located.
2. Double-click the synonym *GetAllEmployees - Web Services* in the navigation pane, then click the *Modeling View* tab. The segment relationships are initially represented as follows:

Notice that both Employee and EmployeeRelative are children of the Response segment in the generated synonym.

Your goal is to report against both segments at the same time, which is not something you can do using this structure. To accomplish that task, you must first make the EmployeeRelative segment a child of the Employee segment, an easy adjustment using the DMC Segment View.
3. Click the Segment View tab. You will see the following pane, in which Employee and Employee Relative are both children of segment Response, as shown in Modeling View:
4. Drag the EmployeeRelative segment and drop it onto the Employee segment. EmployeeRelative is now a child of Employee, as shown in the revised Tree pane.
5. Next, you must set up the relationship that shows how the two segments are joined. Remember that in the schema the Employee segment and the EmployeeRelative segment are joined where EID = ERID.

To mirror this relationship, click the *Ellipsis* (...) for *Keyfld* in the EmployeeRelative segment on the right pane. The Join Properties dialog box opens. This is where you will define the nature of the join relationship between the two segments.

6. In the Venn Diagram box at the bottom left, click the outer portion of the left circle to specify a *Left Outer Join*. This option retrieves all records from the left-hand data source, along with any matching records from the right-hand data source. In this example, that means you will be able to display Employee values in the report even when the employees do not have any relatives.

   **Tip:** For definitions of other Join configurations that are available through the DMC, see *Join Options* on page 2676.

7. At the top of the dialog box, the Left Source Column displays fields from the Employee segment and the Right Source Column displays fields from the EmployeeRelative segment.
Select EID from the left side and ERID from the right side, then click the = sign between them.

8. Click OK to complete the Join and close the Join Properties dialog box.

9. Click the Modeling View tab to verify the modified structure in which EmployeeRelative is a child of Employee, providing the relationship you need to meet your reporting requirements.

Reference: Join Options

This chart defines the Join options that are available in the Venn Diagram box in the Data Management Console.

**Inner Join** indicates that two data sources are connected by an inner join and that only rows that appear in both tables used in the Join are extracted.

**Left Outer Join** indicates that two data sources are connected by a left outer join and that all rows are extracted from the left data source, as well as the columns from the right source that match.

**Right Outer Join** indicates that two data sources are connected by a right outer join and that all rows are extracted from the right data source, as well as the columns from the left source that match.

**Full Outer Join** indicates that two data sources are connected by a full outer join and that all rows are extracted from both data sources.
Cross Join indicates that two data sources are connected by a cross join, or Cartesian product of two tables. It consists of all possible pairs of rows between the two tables.

What Is a WSDL File?

Example:
WSDL Segment for Generating a Master File for FindAddress Web Service
WSDL Document With SOAP Header
WSDL Document With Output Headers
WSDL Document With Mixed Content
WSDL Document With Abstract Input Data Type

Reference:
Multiple Headers

A Web Services Description Language (WSDL) file is an XML document that describes a Web Service. A WSDL file contains the following key elements:

<table>
<thead>
<tr>
<th>WSDL Element</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>definitions</td>
<td>Root element of all WSDL documents. It defines the name of the web service, declares multiple namespaces used throughout the remainder of the document, and contains all the service elements described here.</td>
</tr>
<tr>
<td>types</td>
<td>Describes all the data types used between the client and server. WSDL is not tied exclusively to a specific typing system, but it uses the W3C XML Schema specification as its default choice. If the service uses only XML Schema built-in simple types, such as strings and integers, the types element is not required.</td>
</tr>
<tr>
<td>message</td>
<td>Describes a one-way message, whether it is a single message request or a single message response. It defines the name of the message and contains zero or more message part elements, which can refer to message parameters or message return values.</td>
</tr>
</tbody>
</table>
### Definition

**WSDL Element** | **Definition**
---|---
portType | Combines multiple message elements to form a complete one-way or round-trip operation. For example, a portType can combine one request and one response message into a single request/response operation, most commonly used in SOAP services. Note that a portType can (and frequently does) define multiple operations.

binding | Describes the concrete specifics of how the service will be implemented on the wire. WSDL includes built-in extensions for defining SOAP services, and SOAP-specific information therefore goes here.

service | Defines the address for invoking the specified service. Most commonly, this includes a URL for invoking the SOAP service.

### Example: WSDL Segment for Generating a Master File for FindAddress Web Service

The following shows the elements for the input and output for the FindAddress Web Service function:

```xml
<!-- edited with XMLSpy v5 rel. 3 U (http://www.xmlspy.com)-->

2682 WebFOCUS
The following Access File is generated from the Create Synonym process:

```
SEGNAME=GETADDRESS, CONNECTION=CON06, VERSION=1.1, OBJECT=getAddress,
   ACTION=getAddress, ENCODING=http://schemas.xmlsoap.org/soap/encoding/,
   TARGETNS=http://arcweb.esri.com/v2, STYLE=RPC, $
   ID=ns11, NS=http://www.themindelectric.com/package/
   com.esri.is.services.common.v2.geom/ , $
   FIELD=point, TYPE=Point, NS_ID=ns11, $
   FIELD=coordinateSystem, TYPE=CoordinateSystem, NS_ID=ns11, $
   ID=ns13, NS=http://www.themindelectric.com/package/
   com.esri.is.services.glue.v2.addressfinder/ , $
   FIELD=addressFinderOptions, TYPE=AddressFinderOptions, NS_ID=ns13, $
```

You can use the following procedure to retrieve data from the FindAddress Master File:

```
SET ALL=ON
TABLE FILE FINDADDRESS
PRINT LOCATION.X LOCATION.Y
WHERE FINDADDRESS.HOUSENUMBER EQ '27'
WHERE FINDADDRESS.STREET EQ 'Stevenson Drive'
WHERE FINDADDRESS.ZONE EQ '07746'
WHERE FINDADDRESS.DATASOURCE EQ 'GDT.Streets.US'
END
```

**Example:**  **WSDL Document With SOAP Header**

The Create Synonym process generates an extra group in the root segment to describe the SOAP HEADER layout, as defined in the WSDL document.

The following WSDL describes a SOAP header:

**Binding section:**

```
<input>
   <soap:body use="literal"/>
   <soap:header part="header" message="tns:jobsHeader" use="literal"/>
</input>
```

**Message description:**

```
<message name="jobsHeader">
   <part element="tns:ibsinfo" name="header"/>
</message>
```
**Types section:**

```xml
<xs:element name="ibsinfo">
  <xs:complexType>
    <xs:sequence>
      <xs:element type="xs:string" name="service"/>
      <xs:element type="xs:string" name="method"/>
      <xs:element type="xs:string" name="license"/>
      <xs:element type="xs:string" minOccurs="0" name="disposition"/>
      <xs:element type="xs:string" minOccurs="0" name="Username"/>
      <xs:element type="xs:string" minOccurs="0" name="Password"/>
      <xs:element type="xs:string" minOccurs="0" name="language"/>
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

**The resulting Master File contains:**

```
SEGMENT=LOCATION, SEGTYPE=S0, $
GROUP=HEADER, ALIAS=Header, USAGE=A210, ACTUAL=A210, $
GROUP=IBSINFO, ALIAS=ibsinfo, USAGE=A210, ACTUAL=A210, $
FIELDNAME=SERVICE, ALIAS=service, USAGE=A30, ACTUAL=A30,
  ACCESS_PROPERTY=(NEED_VALUE), $
FIELDNAME=METHOD, ALIAS=method, USAGE=A30, ACTUAL=A30,
  ACCESS_PROPERTY=(NEED_VALUE), $
FIELDNAME/LICENSE, ALIAS=license, USAGE=A30, ACTUAL=A30,
  ACCESS_PROPERTY=(NEED_VALUE), $
FIELDNAME=DISPOSITION, ALIAS=disposition, USAGE=A30, ACTUAL=A30,
  ACCESS_PROPERTY=(NEED_VALUE), $
FIELDNAME=USERNAME, ALIAS=Username, USAGE=A30, ACTUAL=A30,
  ACCESS_PROPERTY=(NEED_VALUE), $
FIELDNAME=PASSWORD, ALIAS=Password, USAGE=A30, ACTUAL=A30,
  ACCESS_PROPERTY=(NEED_VALUE), $
FIELDNAME=LANGUAGE, ALIAS=language, USAGE=A30, ACTUAL=A30,
  ACCESS_PROPERTY=(NEED_VALUE), $
```

**The resulting Access File contains:**

```
SEGNAME=LOCATION, CONNECTION=PSIBS, VERSION=1.1, OBJECT=LOCATION,
  ACTION=EFRM.LOCATIONRequest@test@@, HEADER=HEADER,
TARGETNS=urn:iwaysoftware:ibse:jul2003:LOCATION,
  HEADERNS=urn:schemas-iwaysoftware-com:iwse, STYLE=DOCUMENT, $
```

Note that the SOAP header is generated in the SOAP request if a value is provided (either explicitly in the request or implicitly via default values in the Master File) for at least one of the header components. If no header values are available, the SOAP header is not generated.
Example: **WSDL Document With Output Headers**

The Create Synonym process generates extra output segment(s) to describe the header data returned by a SOAP request. Segments describing the header and body parts of the SOAP response become children of the response segment and siblings to each other.

**WSDL fragment**

```xml
<operation name="TrackMessagesBulk">
  <soap:operation soapAction="http://www.strikeiron.com/TrackMessagesBulk"
    style="document" />
  <input>
    <soap:body use="literal" />
  </input>
  <output>
    <soap:body use="literal" />
    <soap:header message="s0:TrackMessagesBulkResponseInfo"
      part="ResponseInfo" use="literal" />
  </output>
</operation>
```

**Generated Master File**

```
SEGMENT=RESPONSE, SEGTYPE=S0, SEGSUF=XML, PARENT=TRACKMESSAGESBULK
  POSITION=__RESPONSE, $
  FIELDNAME=RESPONSE, ALIAS=Envelope, USAGE=A1, ACTUAL=A1,
    ACCESSPROPERTY=(INTERNAL), $
  FIELDNAME=HEADER, ALIAS=Header, USAGE=A1, ACTUAL=A1,
    ACCESSPROPERTY=(INTERNAL), $
  FIELDNAME=BODY, ALIAS=Body, USAGE=A1, ACTUAL=A1,
    ACCESSPROPERTY=(INTERNAL), $
SEGMENT=HEADER, SEGTYPE=S0, PARENT=RESPONSE, $
  FIELDNAME=RESPONSE, ALIAS=ResponseInfo, USAGE=A1, ACTUAL=A1,
    ACCESSPROPERTY=(INTERNAL), REFERENCE=HEADER, $
  FIELDNAME=RESPONSECODE, ALIAS=ResponseCode, USAGE=I11, ACTUAL=A11,
    REFERENCE=HEADER.RESPONSE, PROPERTY=ELEMENT, $
  FIELDNAME=RESPONSE1, ALIAS=Response, USAGE=A30, ACTUAL=A30,
    REFERENCE=HEADER.RESPONSE, PROPERTY=ELEMENT, $
SEGMENT=BODY, SEGTYPE=S0, PARENT=RESPONSE, $
  FIELDNAME=RESPONSE, ALIAS=TrackMessagesBulkResponse, USAGE=A1,
    ACTUAL=A1, ACCESSPROPERTY=(INTERNAL), REFERENCE=BODY, $
  FIELDNAME=TRACKMESSAGESBULKRESULT, ALIAS=TrackMessagesBulkResult,
    USAGE=A1, ACTUAL=A1, ACCESSPROPERTY=(INTERNAL),
    REFERENCE=BODY.RESPONSE, PROPERTY=ELEMENT, $
```
Reference:  Multiple Headers

The Adapter for Web Services converts multiple header body definitions in the WSDL document into Master File components. Each input header body becomes a separate GROUP description for the input SOAP segment. For each output header body, a special field description is created in the response segment.

Example:  WSDL Document With Mixed Content

Complex data types with the MIXED property are supported in the SOAP response document.

```xml
<xsd:element name="letterBody">
  <xsd:complexType mixed="true">
    <xsd:sequence>
      <xsd:element name="salutation">
        <xsd:complexType mixed="true">
          <xsd:sequence>
            <xsd:element name="name" type="xsd:string"/>
          </xsd:sequence>
        </xsd:complexType>
      </xsd:element>
      <xsd:element name="quantity" type="xsd:positiveInteger"/>
      <xsd:element name="productName" type="xsd:string"/>
      <xsd:element name="shipDate" type="xsd:date" minOccurs="0"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
</xsd:complexType>
</xsd:element>
```

The resulting Master File contains:

```
SEGMENT=LETTERBODY, SECTYPE=S0, $
FIELDNAME=LETTERBODY, ALIAS=letterBody, USAGE=A50, ACTUAL=A50, $
FIELDNAME=SALUTATION, ALIAS=salutation, USAGE=A50, ACTUAL=A50, 
  REFERENCE=LETTERBODY, PROPERTY=ELEMENT, $
FIELDNAME=NAME, ALIAS=name, USAGE=A50, ACTUAL=A50, 
  REFERENCE=SALUTATION, PROPERTY=ELEMENT, $
FIELDNAME=QUANTITY, ALIAS=quantity, USAGE=P32, ACTUAL=A32, 
  REFERENCE=LETTERBODY, PROPERTY=ELEMENT, $
FIELDNAME=PRODUCTNAME, ALIAS=productName, USAGE=A50, ACTUAL=A50, 
  REFERENCE=LETTERBODY, PROPERTY=ELEMENT, $
FIELDNAME=SHIPDATE, ALIAS=shipDate, USAGE=YYMD, ACTUAL=A10, MISSING=ON, 
  REFERENCE=LETTERBODY, PROPERTY=ELEMENT, $
```
The Adapter for Web Services does not preserve the original sequence of text components and descendant elements. The following SOAP response document and report illustrate this limitation:

```xml
<letterBody>
  <salutation>Dear Mr. Robert Smith.</salutation>
  Your order of
  <quantity>1</quantity> <productName>BabyMonitor</productName>
  shipped from our warehouse on
  <shipDate>1999-05-21</shipDate>.
</letterBody>
```

<table>
<thead>
<tr>
<th>LETTERBODY</th>
<th>SALUTATION</th>
<th>NAME</th>
<th>QUANTITY</th>
<th>PRODUCTNAME</th>
<th>SHIPDATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your order of</td>
<td></td>
<td></td>
<td>1</td>
<td>BabyMonitor</td>
<td>1999/05/21</td>
</tr>
</tbody>
</table>

**Example: WSDL Document With Abstract Input Data Type**

The adapter generates an input field with ACTUAL and USAGE formats of A1. The ACCESS property for this field is initially set to INTERNAL to prevent a front-end tool from requesting an input value. A user can modify the definition manually, if necessary.

**Message description:**

```xml
<message name="ivpIn">
  <part element="m1:ivp" name="parameters"/>
</message>
```

**Input message definition:**

```xml
<xs:element name="ivp">
  <xs:complexType>
    <xs:sequence/>
  </xs:complexType>
</xs:element>
```

The resulting Master File contains:

```
FIELDNAME=IVP, ALIAS=ivp, USAGE=A1, ACTUAL=A1, ACCESSPROPERTY=(INTERNAL), $
```
Mapping Attributes and Default Values

Example:

WSDL Document With Mapped Attributes and Default Values

Element attributes are supported as part of the service input message definition:

- Restriction values are stored in the corresponding field definition of the Master File as an ACCEPT list.
- The default value is stored in the XDEFAULT parameter.

Example:  WSDL Document With Mapped Attributes and Default Values

```xml
<xs:element name="component">
  <xs:complexType>
    <xs:simpleContent>
      <xs:extension base="xs:string">
        <xs:attribute use="optional" default="browse" name="perform">
          <xs:simpleType>
            <xs:restriction base="xs:string">
              <xs:enumeration value="browse"/>
              <xs:enumeration value="insert"/>
              <xs:enumeration value="update"/>
            </xs:restriction>
          </xs:simpleType>
        </xs:attribute>
      </xs:extension>
    </xs:simpleContent>
  </xs:complexType>
</xs:element>
```

The resulting Master Files contains:

FIELDNAME=COMPONENT, ALIAS=component, USAGE=A30, ACTUAL=A30,
ACCESS_PROPERTY=(NEED_VALUE), $

FIELDNAME=PERFORM, ALIAS=perform, USAGE=A6, ACTUAL=A6,
ACCESS_PROPERTY=(NEED_VALUE),

XDEFAULT='browse',
ACCEPT='browse' OR 'insert' OR 'update',
REFERENCE=COMPONENT, PROPERTY=ATTRIBUTE, $

Note that if no explicit value is provided for the field, the XDEFAULT value is used when the SOAP request is generated.
Using Arrays as Input Values

Example:

Using Arrays as Input Values

The Adapter for Web Services supports the use of arrays as input values. An array is described in the Master File using the GROUP definition with ACCESS_PROPERTY=ARRAY_ITEM. GROUP describes one instance of an object. You can provide input values for the array of objects using the following methods:

- Specify lazy OR screening conditions for individual fields in a GROUP.
- Specify lazy OR screening conditions for the GROUP itself. (Values for the individual GROUP fields must be separated by /).
- Read values from a file specified as follows:

  \[
  \text{(IF \ group EQ (ddname))}
  \]

  Only the GROUP describing an array can be used in an in-file construct. For example:

  \[
  \text{FILEDEF CARRAY DISK C:\Users\\.........\countryarray.ftm}
  \]

  Note that only the last screening value is reported for an input array component.

Example: Using Arrays as Input Values

In the following example a segment defining the structure of an ESRI SOAP request retrieves a list of coordinates for the set of addresses. GROUP ADDRESSES are used to define one object item from the ADDRESSES array. The GROUP definition is extended by adding ACCESSPROPERTY=ARRAY_ITEM and providing input values for the fields that comprise the array.
Master File

GROUP=ADDRESSES, ALIAS=addresses, USAGE=A210, ACTUAL=A210,
ACCESSPROPERTY=ARRAY_ITEM, 
  FIELDNAME=HOUSENUMBER, ALIAS=houseNumber, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESSPROPERTY=(NEED_VALUE), XDEFAULT='2815', 
  FIELDNAME=STREET, ALIAS=street, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESSPROPERTY=(NEED_VALUE), XDEFAULT='PRAIRIE AVE.', 
  FIELDNAME=INTERSECTION, ALIAS=intersection, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESSPROPERTY=(NEED_VALUE), 
  FIELDNAME=CITY, ALIAS=city, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESSPROPERTY=(NEED_VALUE), XDEFAULT='MIAMI BEACH', 
  FIELDNAME=STATEProv, ALIAS=state_prov, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESSPROPERTY=(NEED_VALUE), XDEFAULT='FL', 
  FIELDNAME=ZONE, ALIAS=zone, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESSPROPERTY=(NEED_VALUE), XDEFAULT='33140', 
  FIELDNAME=COUNTRY, ALIAS=country, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESSPROPERTY=(NEED_VALUE), XDEFAULT='US', 
GROUP=ADDRESSFINDEROPTIONS, ALIAS=addressFinderOptions, USAGE=A30, 
  ACTUAL=A30, 
  FIELDNAME=DATASOURCE, ALIAS=dataSource, USAGE=A30, ACTUAL=A30,
  MISSING=ON, ACCESSPROPERTY=(NEED_VALUE), XDEFAULT='GDT.Streets.US', 
  FIELDNAME=TOKEN, ALIAS=token, USAGE=A120, ACTUAL=A120,
  ACCESSPROPERTY=(NEED_VALUE, AUTHTOKEN), 
  FIELDNAME=__RESPONSE, USAGE=TX80L, ACTUAL=TX,
  ACCESSPROPERTY=(INTERNAL), 

Note: Although not illustrated in this example, you can use the
ACCESSPROPERTY=ARRAY_ITEM value to create nested GROUP definitions in which an
inner GROUP object serves as an array inside an array. Using nested arrays, you can describe
virtually any hierarchical object.

Screening on Leaf Components

Following are illustrations of the two variations on lazy OR screening on leaf components.

Note that it is not necessary to provide values for all fields in a GROUP since XML array item
objects can be built with the subset of object components. However, the two screening
methods have different conventions for dealing with missing values, as illustrated in the
following examples.

Both of these requests produce identical elements in the MATCH array.

Explicit screening by field

When you are specifying lazy OR screening conditions for individual fields in a GROUP, the
number of values and their positions must be the same for all field in the array GROUP.
Notice that each field below has three values. When an array is generated from this input, the first values in each line will be aligned, the seconds values will be aligned, and the third values will be aligned. Therefore, if values are omitted or misplaced, the alignment will be incorrect.

IF HOUSENUMBER EQ '2815' OR 'Two' OR '1250'
IF STREET EQ 'PRAIRIE AVE.' OR 'Penn Plaza' OR 'Broadway'
IF CITY EQ 'MIAMI BEACH' OR 'NY' OR 'NY'
IF STATE_PROV EQ 'FL' OR 'NY' OR 'NY'
IF ZONE EQ '33140' OR '10121' OR '10001'
IF COUNTRY EQ 'US' OR 'US' OR 'US'

Note that there are no values for the INTERSECTION field in this screening request. When specifying individual fields explicitly you can simply omit any fields you are not interested in including in the array.

**Screening for a whole group**

When you specify lazy OR screening conditions for the GROUP, values for individual fields in the GROUP must be separated by a slash (/). Missing values like INTERSECTION must be accounted for using two consecutive slashed (/) on each line of the screening request.

IF COUNTRY EQ '2815/PRAIRIE AVE./MIAMI BEACH/FL/33140/US' OR 'Two/Penn Plaza//NY/NY/10121' OR '1250/Broadway//NY/NY/10001'

In this example, INTERSECTION is represented by // after STREET and before CITY.

**Using Arrays as Input Values for XML Elements and Their Attributes**

**Example:**

Using Arrays as Input Values for an XML Element and its Attributes

You can apply standard Web Services array methodology to XML attribute values that are associated with parent XML array element values. The Parent array element is described with the ARRAY_ITEM value in the ACCESS_PROPERTY parameter. Associated attributes are linked to the parent element using the REFERENCE parameter, with the PROPERTY parameter set to ATTRIBUTE. You can supply input values for the element and attributes as you would for a regular array.
**Example:** Using Arrays as Input Values for an XML Element and its Attributes

**Master File fragment:**

FIELDNAME=KEY, ALIAS=key, USAGE=A30, ACTUAL=A30,
ACCESS_PROPERTY=(ARRAY_ITEM), $
FIELDNAME=NAME, ALIAS=name, USAGE=A30, ACTUAL=A30,
ACCESS_PROPERTY=(NEED_VALUE), REFERENCE=KEY, PROPERTY=ATTRIBUTE, $

**Request fragment with screening statements:**

IF KEY EQ 'SHARE' OR 'BAE01A'
IF NAME EQ 'Setid' OR 'Location'

**Generated SOAP request:**

The screening statements yield an array of key/name occurrences in the soap request:

```xml
<SOAP-ENV:Body>
  <m:GetQuote xmlns:m="http://ws.cdyne.com/">
    <m:key xsi:type="xsd:string" name="Setid" >SHARE</m:key>
    <m:key xsi:type="xsd:string" name="Location" >BAE01A</m:key>
  </m:GetQuote>
</SOAP-ENV:Body>
```

**Modifying Namespace Qualifiers in WSDL Schemas**

Namespace qualifiers are generated in the SOAP request document in accordance with the WSDL schemas. You can modify qualification rules in the Access File to affect how the SOAP XML request is built.

Qualification control information is stored in the Access File on the segment, namespace (Id), and element/attribute (Master File field) levels.

- **Segment level qualification** governs qualifiers for all element/attributes in the Body/Header, respectively, belonging to the target namespace. Segment level qualification information is taken from the schema level for the target namespace.

- **ID level qualification** governs qualifiers for all element/attributes in the described namespace. ID level qualification information is taken from the particular namespace corresponding to the referenced schema.

- **Field level qualification** governs qualifiers for the particular element/attribute and overwrites Segment/ID settings. Field level qualification is taken from the particular schema element type definition.

New parameters are introduced in the Access File in both the Segment and ID records:

- **ELEMFORM** and **ATTRFORM** (for the SOAP Body).
- **HELEMFORM** and **HATTRFORM** (for the SOAP Header).
A new FORM parameter is introduced in the Field record that describes the element or attribute.

Acceptable values for the new parameters are qualified and unqualified.

The default behavior (full qualification for all elements in the Header and Body, and no qualification for the attributes) is applied when no new parameters are found in the Access File.

See the XML Schema Part 0: Primer, which you can access at http://www.w3.org/TR/2001/REC-xmlschema-0-20010502/#NS, for details about Advanced Concepts: Namespaces, Schemas & Qualification.

### Data Type Support

The following table lists how the server maps XSD data types in a Master File.

<table>
<thead>
<tr>
<th>XSD Data Type</th>

Date-Time Processing

**How to:**
Enable ISO Standard Date-Time Notation

Date-time formats can produce output values and accept input values that are compatible with the ISO 8601:2000 date-time notation standard.

**Syntax:**
How to Enable ISO Standard Date-Time Notation

`SET DTSTANDARD = {OFF|ON|STANDARD|STANDARDU}`

where:

**OFF**
- Does not provide compatibility with the ISO 8601:2000 date-time notation standard.

**ON|STANDARD**
- Enables recognition and output of the ISO standard formats, including use of T as the delimiter between date and time, use of period or comma as the delimiter of fractional seconds, use of Z at the end of "universal" times, and acceptance of inputs with time zone information. STANDARD is a synonym for ON.

**STANDARDU**
- Enables ISO standard formats (like STANDARD) and also, where possible, converts input strings to the equivalent "universal" time (formerly known as "Greenwich Mean Time"), thus enabling applications to store all date-time values in a consistent way.

### Capturing a SOAP Request Using FILEDEF SOAPTSCQ in a Procedure

**Example:**
Using FILEDEF SOAPTSCG to Capture a SOAP Request

You can use the command FILEDEF SOAPTSCQ within a procedure to capture the SOAP request being generated and store it in a designated location in the file system. Since the SOAP request itself is not actually executed, 0 records are returned in the report.
**Example:** Using FILEDEF SOAPTSCQ to Capture a SOAP Request

In this example, the procedure reports against a Web Service operation that has the two parameters: SYMBOL and USERNAME. The generated SOAP request is stored in a file called SOAPrequest.xml.

```plaintext
FILEDEF SOAPTSCQ DISK C:\IBI\APPS\XIGNITE\SOAPrequest.xml
TABLE FILE XQUOTES_GETQUOTE
PRINT SYMBOL1 LAST
WHERE SYMBOL EQ 'IBM'
WHERE USERNAME EQ 'myusername'
END
```

The following is the content of SOAPrequest.xml after the procedure is executed:

```xml
<soap_tscq>
<soap_url>http://www.xignite.com/xQuotes.asmx</soap_url>
<soap_action>http://www.xignite.com/services/GetQuote</soap_action>
<soap_body>
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:tns="http://www.xignite.com/services/">
  <SOAP-ENV:Header>
    <m:Header xmlns:m="http://www.xignite.com/services/">
      <m:Username xsi:type="xsd:string">myusername</m:Username>
    </m:Header>
  </SOAP-ENV:Header>
  <SOAP-ENV:Body>
    <m:GetQuote xmlns:m="http://www.xignite.com/services/">
      <m:Symbol xsi:type="xsd:string">IBM</m:Symbol>
    </m:GetQuote>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
</soap_body>
</soap_tscq>
```
The Adapter for Words Analysis can be used to analyze the content of textual data. It counts the occurrence of each word within the text, and can display the results as a tabular report or graph (for example, a Tag Cloud Graph). Words that are defined in a stop words file, such as wan_stopwords_ibi.txt, are not included in the analysis.

**Topics:**
- Configuring the Adapter for Words Analysis
- Creating Synonyms With the Adapter for Words Analysis
Configuring the Adapter for Words Analysis

How to:
Configure the Adapter for Words Analysis

You can configure the Adapter for Words Analysis from the Web Console or the Data Management Console.

Procedure: How to Configure the Adapter for Words Analysis

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click **Adapters**.
   
   or

   From the Data Management Console, expand the **Adapters** folder.
   The Adapters folder opens.

2. Expand the **Available** folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select **Configure**.
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click **Configure**. The configured adapter is added to the Adapters list in the navigation pane.

Note: The Adapter for Words Analysis is under the **Social Media** group folder. No input parameters are required.

Creating Synonyms With the Adapter for Words Analysis

How to:
Create a Synonym

After configuring the Adapter for Words Analysis, a set of predefined synonyms and example procedures (FOCEXECs) can be created for this adapter.
Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click Adapters.
   
The Adapters page opens.

2. Right-click Words Analysis and select Create Synonym from the drop-down menu.
   
The Select candidate(s) for Words Analysis Synonym(s) page opens, as shown in the following image.

3. Enter a folder name in the Application field or click the selector button (...) and navigate to one.

4. Click Create Synonym.
The synonyms and sample procedures are created in the application folder, as shown in the following image.

**Note:**

- The metadata (Master Files and Access Files) is created in the parent folder.
- The Create Synonym process also loads a number of sample reports into the `wansamp` subfolder that can be run out-of-the-box. These reports use sample text that is loaded during the Create Synonym process.
XBRL® is a language for the electronic communication of business and financial data. It provides major benefits in the preparation, analysis, and communication of business information.

Companies can use XBRL to save costs and streamline their processes for collecting and reporting financial information. Consumers of financial data, including investors, analysts, financial institutions and regulators, can receive, find, compare and analyze data much more rapidly and efficiently if it is in XBRL format.

The Adapter for XBRL allows applications to access XBRL documents.

Topics:

- Reporting on Dimensions
What Is XBRL?

**Example:**
Sample XBRL

**Reference:**
XBRL Terminology

XBRL stands for *eXtensible Business Reporting Language*. It is one of a family of XML languages, which is becoming a standard means of communicating financial data between businesses and on the internet. Instead of treating financial information as a block of text, as in a standard internet page or a printed document, it provides an identifying tag for each individual item of data. This is computer readable. For example, company net profit has its own unique tag. However, these tags are more than simple identifiers. They provide a range of information about the item, such as whether it is a monetary item, percentage, or fraction. XBRL allows labels in any language to be applied to items, as well as accounting references or other subsidiary information.

XBRL can show how items are related to one another. It can thus represent how they are calculated. It can also identify whether they fall into particular groupings for organizational or presentational purposes.

**XBRL Taxonomies** are the dictionaries that the language uses. These are the categorization schemes that define the specific tags for individual items of data (such as "net profit"). National jurisdictions have different accounting regulations, so each may have its own taxonomy for financial reporting. Many different organizations, including regulators, specific industries, or even companies, may also require taxonomies to cover their own business reporting needs. A special taxonomy has also been designed to support collation of data and internal reporting within organizations. This is the GL taxonomy.
Example: Sample XBRL

Below is a small example of XBRL:

```
<ifrs-gp:AssetsHeldSale contextRef="Current_AsOf" unitRef="U-Euros"
    decimals="0">100000</ifrs-gp:AssetsHeldSale>
<ifrs-gp:ConstructionProgressCurrent contextRef="Current_AsOf"
    unitRef="U-Euros" decimals="0">100000</ifrs-gp:ConstructionProgressCurrent>
<ifrs-gp:Inventories contextRef="Current_AsOf" unitRef="U-Euros"
    decimals="0">100000</ifrs-gp:Inventories>
<ifrs-gp:OtherFinancialAssetsCurrent contextRef="Current_AsOf"
    unitRef="U-Euros" decimals="0">100000</ifrs-gp:OtherFinancialAssetsCurrent>
<ifrs-gp:HedgingInstrumentsCurrentAsset contextRef="Current_AsOf"
    unitRef="U-Euros" decimals="0">100000</ifrs-gp:HedgingInstrumentsCurrentAsset>
<ifrs-gp:CurrentTaxReceivables contextRef="Current_AsOf" unitRef="U-
    Euros" decimals="0">100000</ifrs-gp:CurrentTaxReceivables>
<ifrs-gp:TradeOtherReceivablesNetCurrent contextRef="Current_AsOf"
    unitRef="U-Euros" decimals="0">100000</ifrs-gp:TradeOtherReceivablesNetCurrent>
<ifrs-gp:PrepaymentsCurrent contextRef="Current_AsOf" unitRef="U-Euros"
    decimals="0">100000</ifrs-gp:PrepaymentsCurrent>
<ifrs-gp:CashCashEquivalents contextRef="Current_AsOf" unitRef="U-
    Euros" decimals="0">100000</ifrs-gp:CashCashEquivalents>
<ifrs-gp:OtherAssetsCurrent contextRef="Current_AsOf" unitRef="U-Euros"
    decimals="0">100000</ifrs-gp:OtherAssetsCurrent>
<ifrs-gp:AssetsCurrentTotal contextRef="Current_AsOf" unitRef="U-Euros"
    decimals="0">1000000</ifrs-gp:AssetsCurrentTotal>
```
What Is XBRL?

Below is what the XBRL example represents:

![Current Assets Table]

**Reference:** XBRL Terminology

The following chart lists and defines XBRL terminology.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>abstract element</td>
<td>An element for which the attribute abstract in its XML schema declaration has the value &quot;true&quot; and which, therefore, cannot be used in an XML instance.</td>
</tr>
<tr>
<td>aggregator</td>
<td>A dimension member that represents the result of summing facts about other members of the same dimension.</td>
</tr>
<tr>
<td></td>
<td>Example: In the products dimension, the member &quot;TotalProducts&quot; is the aggregator of all possible products.</td>
</tr>
<tr>
<td></td>
<td>See dimension member.</td>
</tr>
<tr>
<td>alias concept</td>
<td>The concept at the &quot;to&quot; end of a definition arc with arc role <a href="http://www.xbrl.org/2003/arcrole/essence">http://www.xbrl.org/2003/arcrole/essence</a> alias.</td>
</tr>
<tr>
<td></td>
<td>Alias and essence concepts have the same definition in the sense that valid values for an alias concept are always valid values for essence concepts to which they are related by an essence-alias relationship.</td>
</tr>
<tr>
<td>alias item</td>
<td>An item in an instance whose element is an alias concept.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>arc</td>
<td>Arcs relate concepts to each other by associating their locators. Arcs also associate concepts with resources by connecting the concept locators to the resources themselves. Arcs are also used to connect fact locators to footnote resources in footnote extended links. Arcs have a set of attributes that document the nature of the relationships expressed in extended links. Importantly all arcs have an xlink:arcrole attribute that determines the semantics of the relationship they describe.</td>
</tr>
<tr>
<td>c-equal</td>
<td>Context-equal: Items or sets or sequences of items having the same item type in s-equal contexts.</td>
</tr>
</tbody>
</table>
| ancestor, child, descendant, grandparent, parent, sibling, uncle | Relationships among elements in an XBRL instance: using the terminology of [XPATH], for any element E, another element F is its:  
- ancestor only if F appears on the ancestor axis of E.  
- child only if F appears on the child axis of E.  
- descendant only if F appears on the descendant axis of E.  
- grandparent only if F is the parent of the parent of E.  
- parent only if F appears on the parent axis of E.  
- sibling only if F appears on the child axis of the parent of E and is not E itself.  
- uncle only if F is a sibling of the parent of E. |
<p>| concept                 | Concepts are defined in two equivalent ways. In a syntactic sense, a concept is an XML Schema element definition, defining the element to be in the item element substitution group or in the tuple element substitution group. At a semantic level, a concept is a definition of a kind of fact that can be reported about the activities or nature of a business activity. |
| concrete element        | An element for which the attribute abstract in its XML schema declaration has the value &quot;false&quot; and which, therefore, may appear in an XML instance. |</p>
<table>
<thead>
<tr>
<th><strong>Term</strong></th>
<th><strong>Definition</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>Contexts are elements that occur as children of the root element in XBRL instances. They document the entity, the period and the scenario that collectively give the appropriate context for understanding the values of items.</td>
</tr>
<tr>
<td>dimension</td>
<td>Each one of the different aspects by which a fact may be characterized. A dimension is a (possibly empty or possibly infinite) set of members. A typical example of a dimension is the &quot;product&quot; dimension that identifies for a concept (Sales) each one of the possible products that its fact can be expressed about.</td>
</tr>
<tr>
<td>dimension member</td>
<td>Each one of the possibilities we can choose from the whole Dimension set.</td>
</tr>
<tr>
<td></td>
<td>Example: In the &quot;Products Dimension&quot; each one of the products is a Dimension Member.</td>
</tr>
<tr>
<td>Discoverable Taxonomy Set (DTS)</td>
<td>A DTS is a collection of taxonomy schemas and linkbases. The bounds of a DTS are such that the DTS includes all taxonomy schemas and linkbases that can be discovered by following links or references in the taxonomy schemas and linkbases included in the DTS. At least one taxonomy schema in a DTS must import the xbrl-instance-2003-12-31.xsd schema.</td>
</tr>
<tr>
<td>duplicate items</td>
<td>Two items of the same concept in the same context under the same parent.</td>
</tr>
<tr>
<td>duplicate tuples</td>
<td>Two occurrences of a tuple with all their descendants having the same content. More precisely, tuples that are p-equal, all of whose tuple children have a duplicate (except for being p-equal) in the other tuple, and all of whose item children have a duplicate (except for being p-equal) in the other tuple.</td>
</tr>
<tr>
<td>entity</td>
<td>A business entity, the subject of XBRL items. Where the [XML]/[SGML] concept of syntactic &quot;entity&quot; is meant, this will be pointed out.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>essence concept</td>
<td>The concept at the &quot;from&quot; end of a definition arc with arc role <a href="http://www.xbrl.org/2003/arcrole/essence">http://www.xbrl.org/2003/arcrole/essence</a> alias. Alias and essence concepts are definitionally equivalent in the sense that valid values for an alias concept are always valid values for essence concepts to which they are related by an essence-alias relationship.</td>
</tr>
<tr>
<td>essence item</td>
<td>An item in an instance whose element is an essence concept.</td>
</tr>
<tr>
<td>explicit dimension</td>
<td>Occurs when all the members are named.</td>
</tr>
<tr>
<td></td>
<td>See dimension and dimension member.</td>
</tr>
<tr>
<td>extended link</td>
<td>An extended link is an element identified as an extended link using the syntax defined in the XML Linking Language [XLINK]. Extended links represent a set of relationships between information that they contain and information contained in third party documents.</td>
</tr>
<tr>
<td>fact</td>
<td>Facts can be simple, in which case their values must be expressed as simple content (except in the case of simple facts whose values are expressed as a ratio), and facts can be compound, in which case their value is made up from other simple and/or compound facts. Simple facts are expressed using items (and are referred to as items in this specification) and compound facts are expressed using tuples (and are referred to as tuples in this specification).</td>
</tr>
<tr>
<td>implicit dimension</td>
<td>Occurs when the members are unknown or when the number of members is impractically large to enumerate explicitly.</td>
</tr>
<tr>
<td></td>
<td>See dimension, dimension member, and explicit dimension in this chart.</td>
</tr>
<tr>
<td>instance namespace</td>
<td>The namespace used for XBRL 2.1 instances, <a href="http://www.xbrl.org/2003/instance">http://www.xbrl.org/2003/instance</a></td>
</tr>
</tbody>
</table>
### What Is XBRL?

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>An item is an element in the substitution group for the XBRL item element. It contains the value of the simple fact and a reference to the context (and unit for numeric items) needed to correctly interpret that fact. When items occur as children of a tuple, they must also be interpreted in light of the other items and tuples that are children of the same tuple. There are numeric items and non-numeric items, with numeric items being required to document their measurement accuracy and units of measurement.</td>
</tr>
<tr>
<td>least common ancestor</td>
<td>In an instance, the element that is an ancestor of two elements and has no child that also appears on the ancestor axis [XPATH] of those same two elements.</td>
</tr>
<tr>
<td>linkbase</td>
<td>A linkbase is a collection of XML Linking Language [XLINK] extended links that document the semantics of concepts in a taxonomy.</td>
</tr>
<tr>
<td>linkbase namespace</td>
<td>The namespace of XBRL 2.1 linkbases, <a href="http://www.xbrl.org/2003/linkbase">http://www.xbrl.org/2003/linkbase</a></td>
</tr>
<tr>
<td>locator</td>
<td>Locators supply an XPointer [XPTR] reference to the taxonomy schema element definitions that uniquely identify each concept. They provide an anchor for extended link arcs.</td>
</tr>
<tr>
<td>measure</td>
<td>A measure is an XBRL fact whose context contains dimensions.</td>
</tr>
<tr>
<td></td>
<td><strong>See dimension, concept, and fact in this chart.</strong></td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| MUST, MUST NOT, REQUIRED, SHALL, SHALL NOT, SHOULD, SHOULD NOT, MAY, OPTIONAL | MUST/REQUIRED/SHALL/MUST NOT/SHALL NOT:  
- The definition is an absolute requirement of the specification.  
- The definition is an absolute prohibition of the specification.  
SHOULD/RECOMMENDED: There may be valid reasons in particular circumstances to ignore a particular feature, but the full implications must be understood and carefully weighed before choosing a different course.  
SHOULD NOT/NOT RECOMMENDED: There may exist valid reasons in particular circumstances when the particular behavior is acceptable or even useful, but the full implications should be understood and the case carefully weighed before implementing an behavior described with this label.  
MAY/OPTIONAL: A feature is truly optional. One vendor may choose to include the feature because a particular marketplace requires it or because the vendor feels that it enhances the product while another vendor may omit the same feature. |
<p>| non-numeric item                          | An item that is not a numeric item as defined below. Dates, in particular, are not numeric.                                                                 |
| numeric item                              | An item whose simple content is derived by restriction from the XML Schema primitive types decimal, float or double, or complex content derived by restriction from the XBRL defined type fractionItemType |
| period                                    | An instant or duration of time. In business reporting, financial numbers and other facts are reported &quot;as of&quot; an instant or for a period of certain duration. Facts about instants and durations are both common. |
| p-equal                                   | Parent-equal: instance items or tuples having the same parent.                                                                 |
| resource                                  | Resources are XML fragments, contained within extended links that provide additional information about concepts or items. |</p>
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>root of an XBRL instance</td>
<td>The root of an XBRL instance is the xbrl element. In principle, it is possible to embed an XBRL instance in any XML document. In this case, the xbrl element is the container for the XBRL instance.</td>
</tr>
<tr>
<td>s-equal</td>
<td>Structure-equal: XML nodes that are either equal in the XML value space, or whose XBRL-relevant sub-elements and attributes are s-equal.</td>
</tr>
<tr>
<td>taxonomy</td>
<td>A taxonomy is an XML schema and the set of XBRL linkbases that it references using linkbaseRef elements and the linkbases that are nested within it.</td>
</tr>
<tr>
<td>taxonomy schema</td>
<td>A taxonomy schema is an XML Schema [SCHEMA 1]. A large part of many taxonomy schemas is given over to the definition of the syntax for the concepts in that taxonomy.</td>
</tr>
<tr>
<td>tuple</td>
<td>A tuple is an element in the substitution group for the XBRL tuple element. Tuples are used to bind together the parts of a compound fact. Those constituent parts are themselves, facts but they must be interpreted in light of each other. For example, the name, age and compensation of a director of a company need to be grouped together to be correctly understood.</td>
</tr>
<tr>
<td>unit</td>
<td>Units are XML fragments that occur as children of the root element in XBRL instances. They document the unit of measure for numeric items. Each unit element is only capable of documenting a single unit of measurement.</td>
</tr>
<tr>
<td>u-equal</td>
<td>Unit-equal. u-equal numeric items having the same units of measurement.</td>
</tr>
<tr>
<td>v-equal</td>
<td>Value-equal: c-equal items having either the same non-numeric value, or numeric values that are equal within some tolerance defined by the lesser of their respective precision, implied precision or decimals attributes.</td>
</tr>

## Configuring the Adapter for XBRL

### How to:

**Configure the Adapter**

You can configure the Adapter for XBRL from the Web Console or the Data Management Console.

### Procedure: How to Configure the Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console menu bar, click Adapters.
   
   or
   
   From the Data Management Console, expand the Adapters folder.
   
   The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   
   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.
Reporting Against XBRL Instance Documents

**Note:** The XBRL adapter is under the XML-based group folder. No input parameters are required.

XBRL instances contain business report facts, with each fact corresponding to a concept defined in the supporting taxonomies. XBRL instances also contain contexts and units that provide additional information needed to interpret the facts in the instance.

You can report against a single XBRL instance or against a collection of XBRL instances, making sure that all lines in the taxonomies that comprise the collection are represented, that is, lines that are shared by multiple taxonomies as well as lines that are unique to any taxonomy in the collection.

Supported allocation options are:

- **FILEDEF.** You can use this method to associate a single instance document location, which can be either HTTP or local.
  
  You must issue a FILEDEF if you want to use Developer Studio FML Painter for reporting. For details, see *Associating a Master File With an XBRL Document* on page 2713.

- **IF statement against the INSTANCE_NAME field in the Master File.** You can use this method with single-instance or multiple-instance documents. IF statements support screening criteria on instance locations that can be HTTP, local, or a mixture of the two.
  
  Reporting is based on an instance document from which you can:

  - Show concepts (field names in the Master File).
  
  or

  - Report facts for the concepts.
Associating a Master File With an XBRL Document

**How to:**

Associate a Master File With an XBRL Document

**Example:**

Standard XBRL Master File

Issuing a FILEDEF Command for an XBRL Document

Information Builders supplies a Master File (XBRLR.MAS) in the server’s home/catalog directory that contains all the fields needed for reporting. You can rename the Master File and place it in an application of your choice.

If you wish to use the FML Painter for hierarchical reporting you must issue a FILEDEF command to provide a predefined understanding of the hierarchy that FML Painter needs in order to locate and display the file. For details about this tool, see the *WebFOCUS Creating Financial Reports Version 7 Release 6.1 and Higher* manual.

**Example: Standard XBRL Master File**

```
FILENAME=XBRL, SUFFIX=XBRL,
SEGNAME=INSTANCE, SEGTYPE=S0, $
FIELD= INSTANCE_NAME, ALIAS= NAME, USAGE=A255, ACTUAL=A255,MISSING=OFF,$

SEGNAME=CONCEPT, SEGTYPE=S0, PARENT=INSTANCE, $
FIELD= PARENT, ALIAS= PARENT, USAGE=A60, ACTUAL=A60,MISSING=OFF, $
    PROPERTY=PARENT_OF, REFERENCE=CONCEPT,$
FIELD= CONCEPT, ALIAS= CONCEPT, USAGE=A60, ACTUAL=A60,MISSING=OFF,$
FIELD= LABEL_DESCRIPTION, ALIAS= LABEL, USAGE=A100, ACTUAL=A100,MISSING=ON, $
    PROPERTY=CAPTION, REFERENCE=CONCEPT,$
FIELD= LABEL_LANG, ALIAS= LANG, USAGE=A10, ACTUAL=A10,MISSING=ON, $
    REFERENCE=CONCEPT,$
FIELD= LABEL_TYPE, ALIAS= LABEL_T, USAGE=A40, ACTUAL=A40,MISSING=ON, $
    REFERENCE=CONCEPT,$
FIELD= DOCUMENTATION, ALIAS= DOC, USAGE=A100, ACTUAL=A100,MISSING=ON, $
    REFERENCE=CONCEPT,$
FIELD= ORDER, ALIAS= ORDER, USAGE=P6.2, ACTUAL=A5,MISSING=OFF, $
    REFERENCE=CONCEPT,$
```
How to Associate a Master File With an XBRL Document

**Syntax:**

```plaintext
FILEDEF ddname source filename
```

where:

- **ddname**
  - The logical reference name matching the supplied XBRLR Master File or a renamed version of this Master File.

- **source**
  - The location on disk of the XBRL document.

- **filename**
  - The name of the XBRL instance document, including the qualified path.

**Example:**

**For Windows**, when you have the xbrlr.xml document under C:\, use the following FILEDEF in your profile:

```plaintext
FILEDEF xbrlr disk C:\incomestatement2006Q1.xml
```

**For UNIX**, when you have the xbrlr.xml document under /usera/xml/, use the following FILEDEF in your profile:

```plaintext
FILEDEF xbrlr DISK /usera/xml/incomestatement2006Q1.xml
```

**For z/OS**, when you have the xbrlr.xml document in INCOMESTATEMENT2006Q1.DOC, use the following FILEDEF in your profile:

```plaintext
FILEDEF xbrlr DISK //INCOMESTATEMENT2006Q1.XML.DOC'
```
Reporting on Dimensions

Example:
Sample XBRLRD Master File
Sample XBRLRD Procedure

You can report on grouped concepts based on a hypercube definition. For subsets of data in an XBRL document, the dimension members in the subset are hierarchically related to one another.

Dimensional instances are processed using a unified XBRLRD Master File, which consists of the standard XBRL Master File (as shown in Standard XBRL Master File on page 2713) plus a dimension definition (as shown in Sample XBRLRD Master File on page 2715).

A taxonomy is used to show all concepts and related cubes with hierarchies.

Dimensional reporting enables you to:

- Show concepts and dimensional relations.
- Report facts for the concepts, with related dimensional information referenced in the fact’s context.

Dimension reporting requires that instance documents and taxonomy files be located in the same local directory.

Example: Sample XBRLRD Master File

The hypercube and dimension definitions appear at the end of the standard Master File.

Note that, depending on the structure of your request, you can use this Master File to report on:

- The entire taxonomy.
- Only on concepts that have associated facts.
Only on hypercubes, which group concepts by fact. If dimensions are defined, unless there is a related fact in the taxonomy, the hypercubes will not be displayed. For an illustration of a request that reports on hypercubes, see Sample XBRLRD Procedure on page 2717.

FILENAME=XBRL, SUFFIX=XBRL,
SEGNAME=INSTANCE, SEGTYPE=S0, $  
FIELD= INSTANCE_NAME, ALIAS= NAME, USAGE=A255, ACTUAL=A255,MISSING=OFF,$

FIELD= CUBENAME, ALIAS= CUBENAME, USAGE=A60, ACTUAL=A60,MISSING=OFF,$

SEGNAME=DIMENSION, SEGTYPE=S0, PARENT=HCUBE,$  
FIELD= DIMNAME, ALIAS= DIMNAME, USAGE=A60, ACTUAL=A60,MISSING=OFF,$

SEGNAME=DIMMEMBER, SEGTYPE=S0, PARENT=DIMENSION,$  
FIELD= DIMMEMBER, ALIAS= DIMMEMBER, USAGE=A60, ACTUAL=A60,MISSING=OFF,$  
PROPERTY=PARENT_OF, REFERENCE=DIMMEMBER,$
Example: Sample XBRLRD Procedure

The following request reports against the XBRLRD data source.

FI XBRLRD DISK
C:\COREPTaxonomy1.2.4\CR_EQU_IRB_instance.xml
TABLE FILE XBRLRD
PRINT CONCEPT FACT BY CUBE BY DIMNAME BY DIMMEMPAR BY DIMMEMBER
END
Using the Adapter for XML

The Adapter for XML allows applications to access XML data sources. The adapter traverses the hierarchical trees and returns an answer set to the requesting application.

Topics:
- Preparing the XML Environment
- Configuring the Adapter for XML
- Managing XML Metadata
Preparing the XML Environment

The Adapter for XML does not require any environment variables to be set up.

Configuring the Adapter for XML

You can configure the Adapter for XML from the Web Console or the Data Management Console.

Procedure: How to Configure the Adapter

1. From the Web Console menu bar, click Adapters.
   
or
   From the Data Management Console, expand the Adapters folder.
   
The Adapters folder opens.

2. Expand the Available folder, if it is not already expanded.

3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select Configure.
   
The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click Configure. The configured adapter is added to the Adapters list in the navigation pane.

Note: The XML adapter is under the XML-based group folder. No input parameters are required.
**Associating a Master File With an XML Document**

**How to:**
Associate a Master File With an XML Document

**Example:**
Issuing a FILEDEF Command for an XML Column
Issuing a FILEDEF Command for an XML Collection

You must explicitly issue a FILEDEF command to associate a Master File with an XML document. In order to properly code the FILEDEF command, you need to determine how the XML documents are organized. If the documents are in one file and are described by the same DTD, the organization is called a COLUMN. If there are various documents in one directory and all are described by the same DTD, then the organization is called a COLLECTION.

<table>
<thead>
<tr>
<th>Source</th>
<th>Collection Organization</th>
<th>Column Organization</th>
</tr>
</thead>
<tbody>
<tr>
<td>disk</td>
<td>supported</td>
<td>supported</td>
</tr>
<tr>
<td>http</td>
<td>not supported</td>
<td>supported</td>
</tr>
<tr>
<td>https</td>
<td>not supported</td>
<td>supported</td>
</tr>
</tbody>
</table>

**Syntax:**

How to Associate a Master File With an XML Document

```plaintext
FILEDEF ddname source filename
```

where:

`ddname`
Is the logical reference name matching the desired Master File.

`source`
Is the location of the XML document. Possible values are http, https, and disk.

`filename`
For an XML Column, is the full path to the source file.

For an XML Collection, is the full path to the source directory. The directory name must be followed by the wildcard characters '*. *

```
The file name must start with 'http://' or 'https://' if the XML documents are to be read using an HTTP or HTTPS session.

**Example:** Issuing a FILEDEF Command for an XML Column

**Note:** If you are working on the Web Console or Data Management Console Create Synonym panes, see Synonym Creation Parameters for XML on page 2725 for details about how FILEDEFs are created.

**For Windows,** when you have the ordercol.xml document under C:\, use the following FILEDEF in your profile:

```
FILEDEF ordercol disk C:\ordercol.xml
```

**For UNIX,** when you have the ordercol.xml document under /usera/xml/, use the following FILEDEF in your profile:

```
FILEDEF ordercol DISK /usera/xml/ordercol.xml
```

**For z/OS,** when you have the ordercol.xml document in TEST.XML.DOC, use the following FILEDEF in your profile:

```
FILEDEF ordercol DISK //'TEST.XML.DOC'
```

**For HTTP and HTTPS,** when you have the ordercol.xml document under http://www.test.com/xmltest/ (or https://www.test.com/xmltest/), use the following FILEDEF in your profile:

```
FILEDEF order http http://www.test.com/xmltest/ordercol.xml
```

or

```
FILEDEF order http https://www.test.com/xmltest/ordercol.xml
```

**Example:** Issuing a FILEDEF Command for an XML Collection

**Note:** If you are working on the Web Console or Data Management Console Create Synonym panes, see Synonym Creation Parameters for XML on page 2725 for details about how FILEDEFs are created.

**For Windows,** when you have the order1.xml and order2.xml documents under C:\ORDERS, use the following FILEDEF in your profile:

```
FILEDEF order disk C:\orders\*.*
```

**For UNIX,** when you have the ordercol.xml document under /usera/orders, use the following FILEDEF in your profile:

```
FILEDEF ordercol DISK //'TEST.XML.DOC(dtd)'
```
For z/OS, when you have the order document in TEST.XML.DOC (DTD), use the following FILEDEF in your profile:

FILEDEF order DISK /usera/orders/*.*

Managing XML Metadata

In this section:
- Creating Synonyms
- Accessing XML Documents From a Relational DBMS XML Data Type
- Using Static Joins
- Data Type Support
- Changing the Length of Character Strings
- Changing the Precision and Scale of Numeric Columns
- Conversion
- Numeric Values
- Dates in XML

When the server accesses a data source, it needs to know how to interpret the data that it finds. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the XML data types.
Creating Synonyms

**How to:**
Create a Synonym
Create Synonyms From Schema or DTD Subsets

**Example:**
Creating a Synonym for the XMLSLONG DTD

**Reference:**
Synonym Creation Parameters for XML
Managing Synonyms

Synonyms define unique names (or aliases) for each XML data structure that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given XML document.

**Procedure: How to Create a Synonym**

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console menu bar, click *Applications*.
   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.
   The Select adapter to configure or Select connection to create synonym pane opens.

3. Click a connection for the configured adapter.
   The first of a series of synonym creation panes opens.

4. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

5. After entering the parameter values, click *Create Synonym*.
   The Status pane indicates that the synonym was created successfully.
The synonym is created and added under the specified application directory.

Note:

- You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting Create Synonym.

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see Validation for Special Characters and Reserved Words on page 2821.

Reference: Synonym Creation Parameters for XML

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the Create Synonym button, which generates the synonym based on your entries.

You can create a synonym based on either an XML document or an XML schema/DTD:

- If you want to base the synonym on a XML document, select a document instance (Step 1) and click Create Synonym based on Document Instance to skip to Step 3.

- If you want to base the synonym on an XML schema or DTD, click Next in Step 1 to skip to Step 2.

Select Document Instance parameters (Step 1)

Use HTTP URL

Enables you to select a document instance from a URL. This selection requires a Base Location, Document Name, and Document Extension.

Base Location

Defines the location of the document instance.

- If Use HTTP URL is not selected, enter a physical path or application directory and the XML document name, or click the ellipsis (...) to navigate to the document.

- If Use HTTP URL is selected, enter the http address of a directory that contains the XML document you are using to create the synonym. (This functionality is not available when the XML document is a local file.) The URL must start with http:// or https://.

Document Name

Enter the name of the XML document.
Document Extension

Enter the document extension. The default is xml.

Create Synonym based on Document Instance

Clicking this button enables you to create the synonym from the document instance, skipping Step 2.

Select Data Definition parameters (Step 2)

Use HTTP URL

Enables you to select the schema or DTD from a URL. This selection requires a Base Location, Document Name, and Document Extension.

Base Location

Defines the location of the schema or DTD.

- If Use HTTP URL is not selected, enter a physical path or application directory and the schema or DTD file name, or click the ellipsis (…) to navigate to the file.

- If Use HTTP URL is selected, enter the http address of a directory that contains the scheme or DTD file you are using to create the synonym. (This functionality is not available when the XML document is a local file.) The URL must start with http:// or https://.

Document Name

Enter the name of the schema or DTD.

Document Extension

Enter the document extension. The default is xsd.

Create Synonym parameters (Step 3)

Synonym field names processing options

Validate

Select the Validate check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See Validation for Special Characters and Reserved Words on page 2821 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: ‘’, ‘’, ‘\’, ‘/’, ‘‘, ‘$’. No checking is performed for names.
**Make unique**

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

**Synonym Name**

Indicates the name that will be assigned to the synonym. To assign a different name, replace the displayed value.

**Write**

When using a schema file (.xsd), this option includes more information in the synonym Access File. The additional information reflects CHOICE and SEQUENCE definitions of complex XML data types and is used in XML MODIFY.

**Position**

Defines the XPATH to the element subtree on which the synonym will be based.

**Application**

Select an application directory. The default value is baseapp.

**Prefix/Suffix**

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

**Overwrite Existing Synonyms**

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

**Note:** The connected user must have operating system write privileges in order to recreate a synonym.
Creating a Synonym for the XMLSLONG DTD

Example: XMLSLONG.dtd

```
<!ELEMENT Long_root_element (Long_entity_name,Line*,Comment*)>
<!ATTLIST Long_root_element key CDATA #REQUIRED>
<!ELEMENT Long_entity_name (#PCDATA)>
<!ELEMENT Line (#PCDATA)>
<!ELEMENT Comment (#PCDATA)>
<!ENTITY a "11111111111111111111111111111111111111111111111111111111111">
<!ENTITY b "22222222222222222222222222222222222222222222222222222222222">
<!ENTITY c "33333333333333333333333333333333333333333333333333333333333">
<!ENTITY d "44444444444444444444444444444444444444444444444444444444444">
<!ENTITY e "55555555555555555555555555555555555555555555555555555555555">
<!ENTITY f "66666666666666666666666666666666666666666666666666666666666">
<!ENTITY g "77777777777777777777777777777777777777777777777777777777777">
<!ENTITY h "HELLO HELLO HELLO HELLO HELLO HELLO HELLO HELLO HELLO HELLO">
<!ENTITY i "88888888888888888888888888888888888888888888888888888888888">
<!ENTITY j "12345678901234567890123456789012345678901234567890123456789">
<!ENTITY k "00000000000000000000000000000000000000000000000000000000000">
<!ENTITY l "date">
<!ENTITY n "name">
<!ENTITY p "It is possible to have" >
```

To generate a synonym from the XMLSLONG DTD, enter the following information on the Create Synonym panes of the Web Console or the Data Management Console:

1. Click Next to skip Step 1.
2. In the Base Location field of the Select Data Definition pane (Step 2), enter the path and file name for the DTD or schema, or click the ellipsis (...) and navigate to the file. For example:

```
c:\xml\XMLSLONG.dtd
```
Note: If you are using the ellipsis, enter dtd in the Extension field and click the refresh button, as shown in the following image.

3. Click Next.

4. Enter LONGNAME in the Synonym Name field.

5. Click Create Synonym. The synonym is created and added under the specified application directory (baseapp is the default).

6. Open the baseapp application folder in the navigation pane, right-click the LONGNAME synonym, and choose Edit as Text to view the generated Master File.

7. Right-click the LONGNAME synonym and choose Edit Access File as Text to view the corresponding Access File.
If there is no user-defined entity in the DTD, the Access File contains a $ sign. If there is a user-defined entity in the DTD, then the Access File contains the following for each entity

**Entity_name** | **Entity_value**
---|---

where:

**entity_name**

Is the entity name extracted from the DTD.

**entity_value**

Is the entity value extracted from the DTD.
**Syntax:**

**How to Create Synonyms From Schema or DTD Subsets**

If you want to create a synonym from a large XML schema or DTD, you can improve performance by using a subset based on a given position in the hierarchy. This creates a smaller synonym from a subtree (child element) of the XML root.

The syntax is:

```
CREATE SYNONYM child_element FOR schema.xsd
DBMS XML
AT app_dir
PARMS POSITION=/parent_element/child_element
DROP
END
```

where:

- `child_element` is the subtree from which the synonym is created.
- `schema.xsd` is the schema on which the synonym is based.
- `app_dir` is the application directory where the synonym is created.
- `PARMS POSITION` indicates the position in the schema hierarchy.
- `parent_element` is the parent element located at the top-level of the schema hierarchy.

In the following example, the synonym is created for the chapter subtree. The chapter is a child of the book element, which is located at the top-level of the xmlbook schema hierarchy:

```
CREATE SYNONYM chapter FOR xmlbook.xsd
DBMS XML
AT baseapp
PARMS POSITION=/book/chapter
DROP
END
```

`XPATH=/book` is added to the Access File to indicate the position of chapter (the root segment in the synonym) in the schema hierarchy.

When issuing TABLE requests or writing XML based on the synonym, the actual path of the node is required. Since chapter is not the root node in the original schema, the path from the top of the schema to chapter is `/book/chapter`.)
When writing XML files based on the synonym, the chapter element will be wrapped inside the book element, as in `<book><chapter>...</chapter></book>`.

When reporting on an XML file based on the synonym, you should overlook book since chapter is right under book.

**Reference: Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.</td>
</tr>
<tr>
<td>Edit as Text</td>
<td>Enables you to view and manually edit the Master File synonym. <strong>Note:</strong> To update the synonym, it is strongly recommended that you use the graphical interface provided by the Open option, rather than manually editing the Master File.</td>
</tr>
<tr>
<td>Edit Access File as Text</td>
<td>Enables you to view and manually edit the Access File synonym. <strong>Note:</strong> This option is available only when an Access File is created as part of the synonym.</td>
</tr>
<tr>
<td>Sample Data</td>
<td>Retrieves up to 20 rows from the associated data source.</td>
</tr>
</tbody>
</table>
| Data Profiling                | Data Profiling provides the data characteristics for synonym columns.  
Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls.  
Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls. |
<p>| Refresh Synonym (if applicable)| Regenerates the synonym. Use this option if the underlying object has been altered.                                                         |</p>
<table>

Accessing XML Documents From a Relational DBMS XML Data Type

**How to:**

Access XML Data From an RDBMS Using Web Console or Data Management Console Tools

Access XML Data From an RDBMS Manually

XML documents might be stored in any fields or columns in any data source. Reporting from such documents is supported by defining their structure as subtrees attached to a parent segment which describes the original data.

The synonym creation process must be run against the data in the DBMS and against the XML document. The two Master Files must then be combined to make the XML Master File a child of the Master File created against the DBMS. A FILEDEF is not needed in this instance.

**Procedure:** How to Access XML Data From an RDBMS Using Web Console or Data Management Console Tools

1. Using the Web Console or the Data Management Console Create Synonym facility, generate a synonym for an RDBMS data source that contains a column of XML data. Regardless of the data type used to contain the XML data in the native data source, it will be mapped as a TX column in the Master File synonym. (For example, for DB2 Version 9, the XML data type is mapped to TX; for many RDBMS, the CLOB data type is mapped to TX.)

2. Open the generated Master File in the Synonym Editor. The Master File appears in the right pane in Text View. For example, the Master File for a Progress data source might look as follows:

```plaintext
FILE=XMLPRO1 , SUFFIX=SQLPRO , $
SEGNAME=XMLPRO1 , SEGTYPE=S0 , $
FIELD=FLD1 , FLD1 , A2 , A2 , MISSING=ON , $
FIELD=FLD2 , FLD2 , TX50 , TX , MISSING=ON , $
FIELD=FLD3 , FLD3 , TX50 , TX , MISSING=ON , $
```

Notice that this example has two TX columns, each of which contains different data and requires a separate segment declaration in the Master File.

3. From the DMC, click a column described as TX. The pop-up menu contains the Map External XML option.
The Map External XML option reads the XML data directly and creates the structure. The resulting Master File contains the definition of the XML data, represented as a new segment called SEGSUF=XML, which appears in the Text View pane following the original RDBMS segment. The Master File might look like the following:

```
FILE=XMLPRO1 ,SUFFIX=SQLPRO ,$
SEGNAME=XMLPRO1 ,SEGTYPE=S0 ,$
FIELD=FLD1 ,FLD1 ,A2 ,A2 ,MISSING=ON ,$
FIELD=FLD2 ,FLD2 ,TX50 ,TX ,MISSING=ON ,$
FIELD=FLD3 ,FLD3 ,TX50 ,TX ,MISSING=ON ,$
SEGMENT=ORDER, SEGTYPE=S0, POSITION=FLD2, PARENT=XMLPRO1, SEGSUF=XML, $
  FIELDNAME=ORDER, ALIAS='Order', USAGE=A1, ACTUAL=A1, $
  FIELDNAME=KEY, ALIAS='key', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=CUSTOMER, ALIAS='Customer', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=STATUS, ALIAS='Status', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=TOTALPRICE, ALIAS='TotalPrice', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=DATE, ALIAS='Date', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=PRIORIY, ALIAS='Priority', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=CLERK, ALIAS='Clerk', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=SHIPRIORITY, ALIAS='ShipPriority', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=COMMENT, ALIAS='Comment', USAGE=A10, ACTUAL=A10, $
SEGMENT=PORDER, SEGTYPE=S0, POSITION=FLD3, PARENT=XMLPRO1, SEGSUF=XML, $
  FIELDNAME=PORDER, ALIAS='Order', USAGE=A1, ACTUAL=A1, $
  FIELDNAME=KEY, ALIAS='key', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=CUSTOMER, ALIAS='Customer', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=ADDRESS, ALIAS='Address', USAGE=A10, ACTUAL=A10, $
  FIELDNAME=STATE, ALIAS='State', USAGE=A10, ACTUAL=A10, $
```

**Tip:** If you have a TX column that contains multiple XML formats (for example, a name field and an address field), you can choose Map External XML multiple times to create a separate SEGSUF=XML segment for each format.

4. From the Synonym Editor's File menu, save the updated Master File.

**Procedure: How to Access XML Data From an RDBMS Manually**

Suppose that you have a table in an RDBMS with one or more columns storing XML data. In order to report from the XML data, following these steps:

1. Create the Master File for the relational data source using the format for that DBMS.

```
FILE=XMLPRO1 ,SUFFIX=SQLPRO ,$
SEGNAME=XMLPRO1 ,SEGTYPE=S0 ,$
FIELD=FLD1 ,FLD1 ,A2 ,A2 ,MISSING=ON ,$
FIELD=FLD2 ,FLD2 ,TX50 ,TX ,MISSING=ON ,$
FIELD=FLD3 ,FLD3 ,TX50 ,TX ,MISSING=ON ,$
```
2. Create a Master File for the XML document in the column of the RDBMS table. If there are two XML documents with different formats, you must create a Master File for each one.

3. Manually combine the Master Files. On each root segment for the XML Master File, add three fields: position, parent and segsuf. The POSITION keyword identifies the field containing the XML document. The PARENT field describes the original data source. The field SEGSUF defines the root segment of an XML document representing sub-tree. The total length of all fields in the Master File must not exceed the FOCUS limitation of 32k. If it does, the query will fail.

FILENAME=BASEAPP/ORDER, SUFFIX=XML , $
SEGMENT=ORDER, SEGTYPE=S0, $
FIELDNAME=ORDER, ALIAS='Order', USAGE=A1, ACTUAL=A1, $
FIELDNAME=KEY, ALIAS='key', USAGE=A10, ACTUAL=A10, $
FIELDNAME=CUSTOMER, ALIAS='Customer', USAGE=A10, ACTUAL=A10, $
FIELDNAME=STATUS, ALIAS='Status', USAGE=A10, ACTUAL=A10, $
FIELDNAME=TOTALPRICE, ALIAS='TotalPrice', USAGE=A10, ACTUAL=A10, $
FIELDNAME=DATE, ALIAS='Date', USAGE=A10, ACTUAL=A10, $
FIELDNAME=PRIORITY, ALIAS='Priority', USAGE=A10, ACTUAL=A10, $
FIELDNAME=CLERK, ALIAS='Clerk', USAGE=A10, ACTUAL=A10, $
FIELDNAME=SHIPPRIORITY, ALIAS='ShipPriority', USAGE=A10, ACTUAL=A10, $
FIELDNAME=COMMENT, ALIAS='Comment', USAGE=A10, ACTUAL=A10, $
FILENAME=BASEAPP/PORDER, SUFFIX=XML , $

  FIELDNAME=STATE, ALIAS='State', USAGE=A10, ACTUAL=A10, $
```

Using Static Joins

Example:

Modifying Master and Access Files Produced From Schema Exported by an SQL Server

Sample Join Structures: Original and Modified

You can describe various views of the same physical XML document using Master Files and Access Files.

- In the Master File, you use REFERENCE attributes in field definitions to reflect physical relationships between tags in XML document hierarchies and PARENT attributes, which establish logical hierarchical relationships.

- In the Access File, you use the KEYFLD and IXFLD attributes to identify the XML tags that act as primary/foreign keys in the XML document hierarchies, which establish the logical join relationships. The parent field (foreign key) defined in KEYFLD supplies the value for cross-referencing. The descendant field (primary key) defined in IXFLD contains the corresponding value.

The adapter implements join matching values at run time.
You can use static Joins to create join relationships between hierarchically unrelated integral schema ComplexType definitions using any combination of data nodes.

Any XML tags belonging to these definitions can be used to create join pairs. In addition, you can multiply instances of the same physical segment to reflect logical join relationships as needed.

**Note:** Static (embedded) Joins are not directly supported by the Create Synonym facility. To take advantage of this feature, after a synonym is generated you must modify its Master and Access Files. The Data Management Console Synonym Editor is the recommended tool for such modifications since it provides an easily identifiable segments hierarchy with drag and drop capability and a visual calculator for KEYFLD/IXFLD modifications. Using the Data Management Console, you can quickly add all duplicate segments to the Master File, then delete any unneeded segments.

In some cases, schemas (such as those produced by Microsoft tools and reflecting relationships between the original MS SQL Server database tables) contain proper XML constraints (unique/key/keyref) for describing joins. You can use this information to modify the Master File:

- The elements *unique* and *key* define the primary key for the element (segment).
- The element *keyref* defines the *foreign* key for the element (segment).

For an illustration of such a schema, see *Modifying Master and Access Files Produced From Schema Exported by an SQL Server* on page 2738.

**Example:** Modifying Master and Access Files Produced From Schema Exported by an SQL Server

Suppose that two links exist in the schema defined in the file GetAllEmployeesFullDS.xml between the elements Employee and EmployeeTL (segments EMPLOYEE and EMPLOYEETL in the Master File). Two variations follow:

**Defines EmployeeTL --> Employee joined by EId/EId pair**

In this example, segment EMPLOYEE becomes the child of segment EMPLOYEETL in the Master File, and the Access File describes the foreign and primary keys as follows:

```xml
<xs:unique name="Constraint1" msdata:PrimaryKey="true">
  <xs:selector xpath="./Employee" />
  <xs:field xpath="EId" />
</xs:unique>

<xs:keyref name="EmployeeTl_Employee_EId_EId" refer="Constraint1" msdata:ConstraintOnly="true">
  <xs:selector xpath="./EmployeeTl" />
  <xs:field xpath="EId" />
</xs:keyref>
```
Access File

SEGNAME=EMPLOYEE, KEYFLD=EID, IXFLD=EID, $

Defines Employee -- EmployeeTL joined relationship by TLInformation/EtId pair

In this example, segment EMPLOYEETL becomes the child of segment EMPLOYEE in the Master File, and the Access File describes the foreign and primary keys as follows:

```xml
<xs:unique name="EmployeeTl_Constraint1" msdata:ConstraintName="Constraint1" msdata:PrimaryKey="true">
  <xs:selector xpath=".//EmployeeTl" />
  <xs:field xpath="EtId" />
</xs:unique>

<xs:keyref name="Employee_EmployeeTl_EtId_TLInformation" refer="EmployeeTl_Constraint1" msdata:ConstraintOnly="true">
  <xs:selector xpath=".//Employee" />
  <xs:field xpath="TLInformation" />
</xs:keyref>

Access File

SEGNAME=EMPLOYEETL, KEYFLD=TLINFORMATION, IXFLD=ETID, $

Example: Sample Join Structures: Original and Modified

This example illustrates an original structure without a static join and the modifications made to reflect the use of static Joins.

Original Structure Without Static Joins

```
<table>
<thead>
<tr>
<th>GETEMPLOYEEENTL</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
</tr>
<tr>
<td>02</td>
</tr>
<tr>
<td><strong>DATASTOR</strong></td>
</tr>
<tr>
<td><strong>OBJECTTYPE</strong></td>
</tr>
<tr>
<td><strong>ISOOBJECT</strong></td>
</tr>
</tbody>
</table>

```
In this native structure all child segments have a common parent; the root segment GETALLEMPLOYEERESULTS.

In the corresponding Master File generated as part of the synonym, the PARENT attribute of each segment declaration describes the logical relationships among segments, while the REFERENCE attribute for each field provides information about the physical parent/child relationships among the elements in the file.

**Generated Master File**

```
Modified Master File

In the corresponding Master File, parent/child relationships have been \textit{manually} expanded and rearranged and references have been revised to provide accurate pointers through the new hierarchy.

As you look at this Master File, keep the following information in mind:

- The \textbf{REFERENCE attributes} in the field definitions reflect the physical relationships between elements in XML document hierarchies and the segment level \textbf{PARENT attributes}, which establish logical hierarchical relationships. Notice that for segments that have been added or whose positions in the hierarchy have changed, the \textbf{REFERENCE attribute} in the Master File now generally consists of two parts:
  
  \textit{segment.fieldname}

  As a rule, the adapter attempts to resolve each reference in the current segment. If that cannot be accomplished, it searches for the first occurrence of the \textbf{REFERENCE} in the parent chain. (This is illustrated by the \textbf{REFERENCE attributes} in \textbf{SEGMENT EMPLOYEETL}.) Qualified (two-part) references force the direct resolution in the specified segment. (This is illustrated by the \textbf{REFERENCE attributes} in \textbf{SEGMENT EMPLOYEEERELATIVE}.) Both notations are correct and produce the same result in this example.

- The \textbf{ALIAS attribute} in the Master File maps to the element name in the native xml schema so it cannot be changed. However, since the \textbf{FIELDNAME} is always associated with the \textbf{ALIAS}, the field name can be changed without jeopardizing the reference.

- The \textbf{REFERENCE attribute} points to the field name, hence, if field name is changed all references to it should be changed accordingly.

Modified Access File

The modified Access File shows which keys are used in the logical structure of the Join:

- The parent field (foreign key) defined in KEYFLD supplies the value for cross-referencing.
- The descendant field (primary key) defined in IXFLD contains the corresponding value.

SEGNAME=EMPLOYEETL,       KEYFLD=TLINFORMATION,    IXFLD=ETID,     $
SEGNAME=OADDRESS,         KEYFLD=AIDOFFICIAL,      IXFLD=AID,     $

SEGNAME=EMPLOYEERELATIVE, KEYFLD=EID,              IXFLD=EID,     $

Data Type Support

How to:
Set the Actual and Usage Attributes

The Create Synonym process uses a DTD, XSD, or XML document as the source for creating the synonym. DTDs do not contain data type descriptions, therefore the actual and usage attributes of all fields in the Master File are set to ALPHA data type.

If you try to perform arithmetic operations (-, +, >, <) on fields that are numbers or dates in the XML document but are mapped as ALPHA in the Master File, you may not get the expected results since the arithmetic operations are performed on string literals. To override this problem you may modify the USAGE attribute of a field as described in the following sections.

Note: The data type defined in the ACTUAL attribute of a field must remain as ALPHA.

In order to change the default setting you must issue the SET VARCHAR command.

The following table lists how the server maps XSD data types in a Master File. You can change some of these mapping defaults, as described in Changing the Length of Character Strings on page 2751 and Changing the Precision and Scale of Numeric Columns on page 2753.

<table>
<thead>
<tr>
<th>XSD Data Type</th>
<th>USAGE Attribute</th>
<th>ACTUAL Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>decimal</td>
<td>P20.3</td>

</tbody>
</table>
### Syntax: How to Set the Actual and Usage Attributes

**ENGINE XML SET VARCHAR** {ON | OFF}

The ACTUAL and USAGE attributes of each field in the Master File is set arbitrarily to A10. You can override this setting using the SET FIELDLENGTH command

**ENGINE XML SET FIELDLENGTH** nnn

where:

nnn  
Is the length assigned to actual and usage attributes of all fields in the Master File during the create synonym process. The maximum length is 3000.

### Changing the Length of Character Strings

**How to:**

Switch Between Variable and Fixed-length Strings

Change String Length

By default, when the Adapter for XML creates a synonym, it maps all fields defined as string in the XML schema to 10-byte fixed-length alphanumeric in the Master File. You can change the length (the variability and the number of bytes) using the SET VARCHAR and SET LENGTH commands.
How to Switch Between Variable and Fixed-length Strings

Syntax:

By default, when the Adapter for XML creates a synonym, it maps all fields defined as string in the XML schema to fixed-length alphanumeric in the Master File. You can change this default to variable length using the SET VARCHAR command.

```sql
ENGINE XML SET VARCHAR {ON | OFF}
```

where:

XML

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Maps all fields defined as string in the XML schema to variable-length alphanumeric (AnV) in the Master File’s USAGE and ACTUAL attributes.

OFF

Maps all fields defined as string in the XML schema to fixed-length alphanumeric (A) in the Master File's USAGE and ACTUAL attributes. This is the default.

How to Change String Length

Syntax:

By default, when the Adapter for XML creates a synonym, it maps all fields defined as string in the XML schema to 10-byte alphanumeric in the Master File. You can change this default length using the SET FIELDLENGTH command.

```sql
ENGINE XML XML SET FIELDLENGTH length
```

where:

XML

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

length

Is the length, in bytes, assigned to the ACTUAL and USAGE attributes of all fields defined in the XML schema as string. The maximum length is 3000.
Changing the Precision and Scale of Numeric Columns

**How to:**
Override the Default Precision and Scale

**Example:**
Setting the Precision and Scale Attributes

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

**Tip:** You can change this setting manually or from the Web Console.

**Syntax: How to Override the Default Precision and Scale**

ENGINE XML SET CONVERSION RESET
ENGINE XML SET CONVERSION format RESET
ENGINE XML SET CONVERSION format [PRECISION precision [scale]]
ENGINE XML SET CONVERSION format [PRECISION MAX]

where:

**XML**

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

**RESET**

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

**format**

Is any valid format supported by the data source. Possible values are:

**INTEGER** which indicates that the command applies only to INTEGER columns.

**DECIMAL** which indicates that the command applies only to DECIMAL columns.

**REAL** which indicates that the command applies only to single-precision floating-point columns.

**Note:** Only applies to DB2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.
FLOAT which indicates that the command applies only to double-precision floating-point columns.

**precision**

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

**scale**

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

**MAX**

Sets the precision to the maximum allowable value for the indicated data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>MAX Precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>11</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>18</td>
</tr>
<tr>
<td>REAL</td>
<td>9</td>
</tr>
<tr>
<td>FLOAT</td>
<td>20</td>
</tr>
</tbody>
</table>

**Note:** When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.
Example: Setting the Precision and Scale Attributes

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

ENGINE XML SET CONVERSION INTEGER PRECISION 7

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

ENGINE XML SET CONVERSION FLOAT PRECISION 14 3

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

ENGINE XML SET CONVERSION INTEGER RESET

The following example shows how to set the precision and scale attributes for all fields to the defaults:

ENGINE XML SET CONVERSION RESET

Conversion

The data in an XML document may reflect dates or numeric values, however, all the fields in a Master File synonym are set to the ALPHA data type.

Numeric Values

In order to enable arithmetic operations on numeric fields, the data type specified in the USAGE attribute of a numeric field needs to be modified, depending on the data in the XML document, to one of the following data types: Integer (I), Double Float (D) or Decimal (P). If the data type is modified to Double Float or Decimal, use scale and precision as necessary to describe the data in the XML document.

Furthermore, it is recommended that the length of the ALPHA data type specified in the ACTUAL attribute of the numeric field be modified to reflect the maximum length of the data in the XML document.

Dates in XML

Example: Using Dates in XML

In order to enable arithmetic operations on dates, the data type specified in the USAGE attribute of a date field needs to be modified, depending on the date format used in the XML document, to one of the following data types: YYMD, MDYY or DMYY.
Furthermore, the length of the ALPHA data type specified in the ACTUAL attribute of the date field needs to be modified to 10.

**Note:**

- Once you have set the data type in the Master File to one of the date data types, you must make sure that in each of the XML documents from which you report the date format is the same as the one you defined in the Master File. If the data types differ, an error will result.

- The date format in the answer set is not derived from the date format used in the XML document and is always set to YYYY/MM/DD.

**Example: Using Dates in XML**

<table>
<thead>
<tr>
<th>If in the XML document you have the following format:</th>
<th>Then use USAGE=</th>
</tr>
</thead>
<tbody>
<tr>
<td>1996-01-30</td>
<td>YYMD</td>
</tr>
<tr>
<td>01-30-1996</td>
<td>MDYY</td>
</tr>
<tr>
<td>30-01-1996</td>
<td>DMYY</td>
</tr>
</tbody>
</table>
XA Support

This topic describes XA Transaction Management and implementation specifics.

Topics:
- XA Transaction Management
- Supported Interfaces
- Implementation
- Vendor Specifics
**XA Transaction Management**

An application usually defines steps performed against any given resource in terms of **transactions**.

A **transaction** is a complete unit of work in which:

- Results are either all committed or all rolled back.
- The shared resource is transformed from one valid state to another.
- Changes to shared resources do not become visible outside the transaction until the transaction commits.
- The changes of commit are able to survive system or media failure.

The server has the ability to access multiple data sources and to carry out heterogeneous joins across different data sources. The transaction that describes work done by more than one Resource Manager is called a Global or Distributed Transaction.

Most relational and some non-relational resources are maintained by their Resource Managers. The X/Open Distributed Transaction Processing (DTP) model is a software architecture that allows multiple application programs to access resources provided by multiple resource managers, and allows their work to be coordinated into global transactions.

Read/write applications accessing CICS and IMS transactions, relational data sources, as well as CICS-controlled VSAM data sets are able to perform transactions managed in XA-compliant mode. The Transaction Coordinator component uses a two-phase commit protocol for completion of customer transactions across different database management systems.

Using the XA Transaction Management feature does not require any changes in existing ODBC, JDBC, or WebFOCUS Maintain applications. To activate the XA Transaction Management feature, the server has to be configured in Transaction Coordination Mode, using the Web Console configuration functions. In Transaction Coordination Mode, all requests performed against the listed XA-compliant DBMSs will be processed as XA-distributed transactions, and completed in two-phase commit mode. This guarantees the integrity of data modification on all of the involved DBMSs. It protects part of the data modifications from being committed on one DBMS and terminated on another.

**Supported Interfaces**

**XA-compliant adapters are:**

- DB2 (using CLI interface) on UNIX/Windows/Linux
- DB2 (using CLI Interface with RRS) on z/OS
- Oracle
Microsoft SQL Server (using OLE DB interface)
Informix
Sybase ASE
Ingres II

**Non-XA-compliant adapters are:**
- Adabas Stored Procedures
- CICS Transactions
- Informix CISAM
- Micro Focus CISAM
- IMS Transactions
- IMS
- VSAM CICS

**Implementation**

In order to adhere to the DTP model, the server-implemented Transaction Coordinator provides the ability to manage global transactions. Although the Transaction Coordinator is a private implementation, it fully adheres to the XA protocol in the boundaries of its implementation.

- Because the Transaction Coordinator is a private implementation, it does not have a public interface. There is no mechanism for foreign applications to use the Transaction Coordinator.
- Not every Resource Manager, even XA-compliant, is supported unless explicitly stated.

The implementation specifics of the Transaction Coordinator are:
- It is invoked by a keyword in edaserve.cfg (transaction_coordination_mode=on).
- Every unit of work initiated inside any agent will be started as a global transaction, within this agent.
- Coordination will apply to all currently supported XA-compliant interfaces.
- It cannot be turned off.
- All XA-compliant relational resources will participate, enabled implicitly.
- All non-relational resources can be explicitly disabled from participation.
Vendor Specifics

- All transactions will be in the scope of a global transaction. Each commit/rollback will subsequently begin a transaction.
- No CREATE/DROP TABLE commands in XA mode.

### How to:
Create the XA Configuration File

The implementation specifics for DB2 with CLI on UNIX, Windows, and z/OS are:

- The DB2CLI.INI file must have an entry in the common section
  ```
  [COMMON]
  DISABLEMULTITHREAD=1
  ```
- Only the global file, DB2CLI.INI, can be used. It must reside in:
  - For UNIX/NT, installation home.
  - For z/OS, exported by DSNA0INI variable.

The implementation specifics for DB2 with CLI on z/OS are:

- Requires RRS
- RRSAF in DB2CLI.INI

The implementation specific of MS SQL Server is:

- Required DTS

**Note:** If the client and the serve are on different machines, DTS must be installed on both machines.

The implementation specifics of Sybase are:

- The Sybase XA configuration file is needed.
- No bulk load/fast load functionality in XA, no messages are produced, and insert will operate in normal mode.
- Users can create their XA configuration file and point to it in the profile.
**Syntax:**

How to Create the XA Configuration File

ENGINE SQLSYB SET XACONFIGFILE *path*

**where:**

*path*

Should include file name.
Aggregate Awareness substantially improves the efficiency of queries. In order to use this feature successfully, you need an understanding of the principles of relational adapter operation and knowledge of the RDBMS optimizer.

**Topics:**
- Relational Adapters and Aggregated SQL Queries
- Aggregate Awareness in an RDBMS
Relational Adapters and Aggregated SQL Queries

Relational adapters construct optimized SQL queries based on a WebFOCUS request and the hierarchical structure of a file. A relational adapter always attempts to construct an SQL query that delegates most of the work (such as record screening, joins and aggregation) to the underlying relational engine. The ability of the interface to pass the join and all tests to the RDBMS is a prerequisite to constructing an aggregated SQL query.

If aggregation cannot be passed to the RDBMS, the trace file contains an explanation. Usually, the request or the file hierarchy can be corrected in such a way that aggregation can be passed to the RDBMS.

Aggregate Awareness in an RDBMS

How to:

Set Aggregate Awareness

Reference:

Usage Notes for Aggregate Awareness

When aggregation is delegated to the RDBMS, the RDBMS can perform additional optimization of the query by using a mechanism commonly called Aggregate Awareness. Aggregate Awareness is implemented in DB2, Teradata, Oracle, and some other RDBMSs.

The implementation is similar in most RDBMSs. Based on most common types of reports performed on a database, the database administrator creates one or more objects (named SUMMARY TABLES in DB2, JOIN INDEXES in Teradata, and MATERIALIZED VIEWS or SNAPSHOTS in Oracle) that are populated with pre-aggregated data. The size of the pre-aggregated object (summary table, join index, or snapshot) is usually much smaller than the combined size of the involved tables. The RDBMS optimizer evaluates the incoming queries and, if possible, reconstructs the incoming query so that the pre-aggregated data is used for forming the answer set. This significantly reduces both CPU time and I/O operations.

The aggregated SQL generated by the relational adapter is fully suitable for an RDBMS optimizer to use pre-aggregated data. However, DB2, Teradata, and Oracle optimizers have specific rules for when to use pre-aggregated data.

Syntax: How to Set Aggregate Awareness

```
SET AGGREGATE_AWARENESS {FRESH_ONLY|OLD_OK|OFF}
```

where:

```
FRESH_ONLY
```

Sets different values for the parameters associated with each RDBMS.
OLD_OK
Sets different values for the parameters associated with each RDBMS.

OFF
If no option is selected, the behavior of the target RDBMS is determined by the database configuration options. There is no default for this setting.

Reference: Usage Notes for Aggregate Awareness

Adapter-specific parameters for which values are set by the FRESHONLY and OLD_OK settings:

- For DB2, CURRENT REFRESH AGE and CURRENT QUERY OPTIMIZATION.
- For Oracle, QUERY_REWRITE_INTEGRITY and QUERY_REWRITE_ENABLED.
  These values can be set in the Server profile or as a part of an RPC using Direct Passthru.
- Teradata handles aggregate awareness internally.

RDBMS manuals should be reviewed for recommendations, but the most common checklist items are:

- Updating statistics on the pre-aggregated object and the master tables: (RUNSTATS in DB2, COLLECT STATISTICS in Teradata, ANALYZE TABLE in Oracle).
- Confirming compatibility of the generated SQL query and the query used for creating the pre-aggregated object. The most common items are compatibility of:
  - Aggregators (columns functions) and aggregation objects (column function arguments)
  - GROUP BY clauses
  - Joins
Cluster Join

This topic describes the Master File SEGSUF attribute, which enables you to create heterogeneous cluster joins, for example, between data sources of different types.

Topics:
- Embedded Joins
- Embedded Join Master Files
Embedded Joins

An embedded join is an equijoin that you define in a Master File. The name comes from the fact that the join definition is "embedded" in the Master File. (This is also known as a cluster join.)

You can define an embedded join between data sources:

- **Data sources of the same type.** For example, you can define an embedded join between two DB2 tables. This is known as a homogeneous embedded join.

- **Data sources of different types.** For example, you can define an embedded join between three DB2 tables, three CA-IDMS/DB records, and one IMS segment. This is known as a heterogeneous embedded join.

In the following heterogeneous embedded join, A = a DB2 table, B = a CA-IDMS/DB record, and C = an IMS segment.

```
A
   /\     /
  B¹  A   B²
 /\    /\  /\  \
B¹  C  A  B²
```

In a Master File, each segment declaration describes one RDBMS table or view, or one record. You can include up to 64 segments in an embedded join.

The entire join structure described by the Master File is referred to as a tree.

A *subtree* is a segment and any directly related descendant segments of the same data source type. A *root subtree* is the subtree at the top of the tree.

There are four subtrees here:

- A-A-A
- B¹-B¹
- B²
- C

Note that B¹-B¹ and B² are separate subtrees because, even though they are of the same data source type, they are not directly related.

The root subtree is A-A-A.
Embedded Join Master Files

How to:
Define an Equijoin in the Master File

Each embedded join segment declaration describes one RDBMS table or view, or one non-RDBMS record. You can include up to 64 segments.

If several Master Files (used only with TABLE requests) include the same table, you can avoid repeating the same description multiple times. Describe the table in one of the Master Files, and use the CRFILE attribute in the other Master Files to access the existing description.

Syntax:  How to Define an Equijoin in the Master File

An embedded equijoin uses the PARENT segment attribute to identify the relationship between tables and/or records.

FILENAME=mtname, SUFFIX=rootsuffix [,,$]
SEGNAME=table1, SEGTYPE= {S0} [,CRFILE=crfile1] [,,$]
   FIELD=name,...,$
   ...$
SEGNAME=table2, [SEGSUF=branchsuffix,] SEGTYPE=relationship,
   PARENT=table1 [,CRFILE=crfile2][,,$]
   FIELD=name,...,$
   ...$
   ...$

where:

mtname
Is the one-character to eight-character name of the embedded join Master File.

rootsuffix
When the Master File describes:

- A homogeneous embedded join, rootsuffix specifies which adapter to use to access the data source.
- A heterogeneous embedded join, rootsuffix specifies which adapter to use to access the highest-level subtree of the join. That is, it specifies which adapter to use to access the tables or records represented by the root segment and all directly-related descendant segments that are of the same DBMS type.
**table1**

Is the SEGNAME value for the root table or record in the embedded join. If this segment references a remote segment description, table1 must be identical to the SEGNAME from the Master File that contains the full definition of the remote data source.

**name**

Is any field name.

**table2**

Is the SEGNAME value for the related table or record. If this segment references a remote segment description, table2 must be identical to the SEGNAME from the Master File that contains the full definition of the remote data source.

**SEGSUF**

Is used in a heterogeneous embedded join to identify the beginning of a new subtree (other than the root subtree), and to specify which adapter to use to access that subtree. A subtree is a segment (representing a table or record) and all directly related descendant segments of the same data source type. You specify SEGSUF in the highest-level segment of the subtree.

**branchsuffix**

Specifies the value of SEGSUF.

**relationship**

Indicates the type of relationship between the table or record and its parent. Possible values are:

- **S0** indicates that the related table is in a one-to-many or many-to-many (non-unique) relationship with the table or record named as its parent.
- **U** indicates that the related table or record is in a one-to-one or a many-to-one (unique) relationship with the table or record named as its parent.
- **KL** references a remote segment description. Indicates that the related table or record is in a one-to-many or many-to-many (non-unique) relationship with the table or record named as its parent.
- **KLU** references a remote segment description. Indicates that the related table or record is in a one-to-one or a many-to-one (unique) relationship with the table or record named as its parent.

**crfile1**

References a remote segment description. Indicates the name of the Master File that contains the full definition of table1.
**crfile2**

References a remote segment description. Indicates the name of the Master File that contains the full definition of **table2**.
Embedded Join Master Files
This topic describes how synonyms are created from COBOL File Descriptions by the following adapters:

- C-ISAM
- Flat and Delimited Flat Files
- CICS Transactions
- IMS
- IMS Transactions
- Millennium
- RMS
- VSAM and VSAM CICS

The information in this appendix is intended to supplement synonym-creation information in the individual adapter chapters.
Creating Synonyms From COBOL File Descriptions

Synonyms define unique names (or aliases) for each file that is accessible from a server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server.

The CREATE SYNONYM command uses COBOL FD translation capabilities to translate the COBOL file definition into an internal metadata format from which a Master File is created.

Controlling the Translation of a COBOL File Description

You can take advantage of a variety of options to control the translation of a COBOL File Description to a Master File. These options are available from the Create Synonym panes in the adapters that use COBOL FDs. If customization options are not selected, default translation setting are applied.

This topic provides supplementary information for several customization options.
## Customization Options for COBOL File Descriptions

You can customize how a COBOL FD is translated by selecting *Customize options* in the Synonym creation pane. The following options are added to the right pane:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>On Error</strong></td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- <em>Continue</em> to continue generating the Master File when an error occurs. Continue is the default value.</td>
</tr>
<tr>
<td></td>
<td>- <em>Abort</em> to stop generating the Master File when an error occurs.</td>
</tr>
<tr>
<td></td>
<td>- <em>Comment</em> to produce a commented Master File when an error occurs.</td>
</tr>
<tr>
<td><strong>Hyphens as</strong></td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- <em>No</em> to remove all hyphens in the COBOL name from the Master File field names.</td>
</tr>
<tr>
<td></td>
<td>- <em>Yes</em> to replace all hyphens in the COBOL name with the underscore character. Yes is the default value.</td>
</tr>
<tr>
<td><strong>Redefines</strong></td>
<td>You may treat COBOL REDEFINE fields in one of three ways. Choose:</td>
</tr>
<tr>
<td></td>
<td>- <em>Segments</em> to describe REDEFINE fields as segments in the Master File. Segments is the default value.</td>
</tr>
<tr>
<td></td>
<td>- <em>Comments</em> to describe REDEFINE fields as comments in the Master File.</td>
</tr>
<tr>
<td></td>
<td>- <em>None</em> to exclude REDEFINE fields altogether.</td>
</tr>
<tr>
<td><strong>Occurs as</strong></td>
<td>Choose <em>Segments</em> to describe OCCURS structures as segments. Otherwise, choose <em>Field</em>. Segments is the default value.</td>
</tr>
<tr>
<td><strong>Alignment</strong></td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- <em>Yes</em> to insert slack bytes into a record to ensure alignment of numeric fields.</td>
</tr>
<tr>
<td></td>
<td>- <em>No</em> to generate Master Files without alignment of slack bytes. No is the default value.</td>
</tr>
</tbody>
</table>
## Controlling the Translation of a COBOL File Description

<table>
<thead>
<tr>
<th><strong>Parameter</strong></th>
<th><strong>Definition</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Hyphens to skip</td>
<td>FD Translator removes characters from the left, up to and including the Nth hyphen (depending on the value of N chosen in the menu).</td>
</tr>
<tr>
<td></td>
<td>- 0 retains the entire COBOL name. 0 is the default value.</td>
</tr>
<tr>
<td></td>
<td>- All removes all prefixes.</td>
</tr>
<tr>
<td>Order fields</td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- Yes to generate Order fields in a Master File.</td>
</tr>
<tr>
<td></td>

</table>
### REDEFINE Fields

**Example:**

Generating REDEFINE Fields

You may treat COBOL REDEFINE fields in one of three ways:

- Describe REDEFINEes as segments in the Master File (enter S for segments).
- Describe REDEFINEes as comments in the Master File (enter C for comments).
- Exclude REDEFINEes altogether (enter N for none).

Describing REDEFINEes as segments gives you immediate access to all first-level REDEFINEes but may still require user customization. Note that nested REDEFINEes are described as comments, even with this option. The Segment option is only available in software releases that support it. Including REDEFINEes as comments allows you to customize the Master File output to select the redefinitions of your choice.

Fields are described as comments with a dollar sign ($) in column one. If you wish to use the redefinition of a field instead of the original definition, delete the first definition, or insert dollar signs ($) in column one, and remove the dollar signs ($) from the redefinition.
Example: Generating REDEFINE Fields

Consider the following COBOL input description:

```
01 CLIENT-REC.
  02 NAME-ADDR-AREA PIC X(57).
  02 NAME-AND-ADDR
     REDEFINES NAME-ADDR-AREA.
     03 NAME          PIC X(20).
     03 STREET        PIC X(15).
     03 CITY          PIC X(15).
     03 STATE         PIC X(2).
     03 ZIP           PIC X(5).
     03 ZIP_NUMERIC   REDEFINES ZIP PIC 9(5).
```

The following three Master Files are generated from this input, depending on the value entered for Generate REDEFINE Fields.

For a value of S:

```
FILE=REDEFS,                      SUFFIX=FIX,                      $
SEGNAME=CLIENSEG,     SEGTYPE=S0,                                   $
GROUP=CLIENTREC,    ALIAS=E01,   USAGE=A57,      ACTUAL=A57,     $
FIELD=NAMEADDRAREA, ALIAS=E02,   USAGE=A57,      ACTUAL=A57,     $
SEGNAME=NAMEASEG,     SEGTYPE=U,   PARENT=CLIENSEG,     OCCURS=1,             POSITION=NAMEADDRAREA,                        $
GROUP=NAMEANDADDR,   ALIAS=E03,   USAGE=A57,      ACTUAL=A57,     $
FIELD=NAME,        ALIAS=E04,   USAGE=A20,      ACTUAL=A20,     $
FIELD=STREET,      ALIAS=E05,   USAGE=A15,      ACTUAL=A15,     $
FIELD=CITY,        ALIAS=E06,   USAGE=A15,      ACTUAL=A15,     $
FIELD=STATE,       ALIAS=E07,   USAGE=A2,       ACTUAL=A2,      $
FIELD=ZIP,         ALIAS=E08,   USAGE=A5,       ACTUAL=A5,      $
$  FIELD=ZIP_NUMERIC,  ALIAS=E09,   USAGE=P5,       ACTUAL=25,      $
```

For a value of C:

```
FILE=REDEFC,                      SUFFIX=FIX,                      $
SEGNAME=CLIENSEG,     SEGTYPE=S0,                                   $
GROUP=CLIENTREC,    ALIAS=E01,   USAGE=A57,      ACTUAL=A57,     $
FIELD=NAMEADDRAREA, ALIAS=E02,   USAGE=A57,      ACTUAL=A57,     $
$  GROUP=NAMEANDADDR,   ALIAS=E03,   USAGE=A57,      ACTUAL=A57,     $
$  FIELD=NAME,        ALIAS=E04,   USAGE=A20,      ACTUAL=A20,     $
$  FIELD=STREET,      ALIAS=E05,   USAGE=A15,      ACTUAL=A15,     $
$  FIELD=CITY,        ALIAS=E06,   USAGE=A15,      ACTUAL=A15,     $
$  FIELD=STATE,       ALIAS=E07,   USAGE=A2,       ACTUAL=A2,      $
$  FIELD=ZIP,         ALIAS=E08,   USAGE=A5,       ACTUAL=A5,      $
$  FIELD=ZIP_NUMERIC, ALIAS=E09,   USAGE=P5,       ACTUAL=25,      $
```
For a value of N:

FILE=REDEFN,  SUFFIX=FIX,  $
SEGNAME=CLIENSEG,  SEGTYPE=S0,  $
GROUP=CLIENTREC,  ALIAS=E01,  USAGE=A57,  ACTUAL=A57,  $
FIELD=NAMEADDRAREA,  ALIAS=E02,  USAGE=A57,  ACTUAL=A57,  $

LEVEL 88 as Comments

Example:
Generating LEVEL 88 as Comments

Level 88 fields in the COBOL FD associate particular values with a field name. Level 88 fields and values are not required in the Master File. However, you can include them as comments. Enter Y (for yes) to include them or N (for no) to exclude them. Including Level 88 fields lets you easily identify values for RECTYPES for those files that require Level 88 fields. (You must manually add the RECTYPE and value. Because many Level 88 fields may occur in a COBOL FD, it is impossible to successfully determine the appropriate RECTYPE fields and values.) Since Level 88 field names typically describe the values they represent, including them as comments is also a way to document the Master File.

Example: Generating LEVEL 88 as Comments

Consider the following COBOL input description:

```cobol
01 EMPL-REC.
   02 EMPL-SOC-SEC-NUM          PIC S9(8) COMP-3.
   02 EMPL-STATUS               PIC X(1).
     88 EMPL-ACTIVE                     VALUE 'A'.
     88 EMPL-INACTIVE                   VALUE 'I'.
     88 EMPL-RETIRED                    VALUE 'R'.
```

The following two Master Files are generated from this input, depending on the value entered for Generate LEVEL 88 as Comments.

For a value of Y:

FILE=LEV88Y,  SUFFIX=FIX,  $
SEGNAME=RECSEG,  SEGTYPE=S0,  $
FIELD=SOCSECNUM,  ALIAS=E01,  USAGE=P9,  ACTUAL=P5,  $
FIELD=STATUS,  ALIAS=E02,  USAGE=A1,  ACTUAL=A1,  $
$ ACTIVE, VALUE 'A'.  $
$ INACTIVE, VALUE 'I'.  $
$ RETIRED, VALUE 'R'.  $

D. Translating COBOL File Descriptions
The Level 88 fields are indented under the field they describe (STATUS). The values are left-justified to include the maximum information in the Master File, when many values are in the COBOL record. If the COBOL Level 88 values exceed one line in the FD, only the first line will be included in the Master File.

For a value of N:

```
FILE=LEV88N,                       SUFFIX=FIX,                      $
SEGNAME=RECSEG,       SEGTYPE=S0,                                   $
FIELD=SOCSECNUM,    ALIAS=E01,   USAGE=P9,       ACTUAL=P5,      $
FIELD=STATUS,       ALIAS=E02,   USAGE=A1,       ACTUAL=A1,      $
```

OCCURS as Segments

**Example:**

- Simple Fixed OCCURS
- Variable OCCURS
- Nested OCCURS

COBOL FD translation supports all forms of COBOL OCCURS structures: fixed, variable, and nested. You may describe OCCURS structures as segments in the Master File or as individual, numbered fields. Enter Y (for yes) to describe OCCURS structures as segments or N (for no) otherwise.

Fixed and nested repeating groups described as segments use the OCCURS clause to describe the number of occurrences of the group. For fixed repeating groups, the OCCURS value is the number of occurrences. For variable OCCURS, the value is the name of the COBOL DEPENDING ON field. The POSITION attribute is used to describe their location in the record, which is reserved in the Master File with an internally generated POSITION field. All internal POSITION fields generated by the translation end with POSN.

Fixed repeating groups described as numbered fields have a unique number appended to the COBOL field name, once for each occurrence. Because the number of occurrences of a variably occurring group is unknown, they cannot be described individually. In fact, if any one of the repeating groups is variable, they are all described as segments, including fixed occurs, regardless of your menu selection.

**Example:**  **Simple Fixed OCCURS**

Consider the following COBOL input description:

```
01  TBL-REC.
   02  TBL-ENTRY OCCURS 2 TIMES.
      03  TBL-AMT-A                  PIC S9(5).
      03  TBL-AMT-B                  PIC S9(5).
```
The translation can generate the following two Master Files from this input, depending on the value entered for Describe OCCURS as Segments.

For a value of Y:

```plaintext
FILE=OCCURSFY,                     SUFFIX=FIX,                      $
SEGNAME=TBLRESEG,     SEGTYPE=S0,                                   $
  GROUP=TBLREC,     ALIAS=E01,   USAGE=A20,      ACTUAL=A20,     $
  FIELD=TBLNENSEGPOSN, ALIAS=E02,   USAGE=A20,      ACTUAL=A20,     $
SEGNAME=TBLENSEG,     SEGTYPE=S0,  PARENT=TBLRESEG,  $
  OCCURS=2,             POSITION=TBLNENSEGPOSN,                        $
  GROUP=TBLENTRY,     ALIAS=E03,   USAGE=A16,      ACTUAL=A10,     $
  FIELD=TBLAMTA,      ALIAS=E04,   USAGE=P6,       ACTUAL=Z5,      $
  FIELD=TBLAMTB,      ALIAS=E05,   USAGE=P6,       ACTUAL=Z5,      $
FIELD=TBLENSEG,     SEGTYPE=S0,  PARENT=TBLRESEG,  $
  OCCURS=2,             POSITION=TBLENSEGPOSN,                        $
  GROUP=TBLENTRY,     ALIAS=E03,   USAGE=A16,      ACTUAL=A10,     $
  FIELD=TBLAMTA,      ALIAS=E04,   USAGE=P6,       ACTUAL=Z5,      $
  FIELD=TBLAMTB,      ALIAS=E05,   USAGE=P6,       ACTUAL=Z5,      $
```

For a value of N:

```plaintext
FILE=OCCURSFN,                     SUFFIX=FIX,                      $
SEGNAME=TBLRESEG,     SEGTYPE=S0,                                   $
  GROUP=TBLREC,     ALIAS=E01,   USAGE=A32,      ACTUAL=A20,     $
  GROUP=TBLENTRY1,    ALIAS=E02,   USAGE=A16,      ACTUAL=A10,     $
  FIELD=TBLAMTA1,     ALIAS=E03,   USAGE=P6,       ACTUAL=Z5,      $
  FIELD=TBLAMTB1,     ALIAS=E04,   USAGE=P6,       ACTUAL=Z5,      $
  GROUP=TBLENTRY2,    ALIAS=E05,   USAGE=A16,      ACTUAL=A10,     $
  FIELD=TBLAMTA2,     ALIAS=E06,   USAGE=P6,       ACTUAL=Z5,      $
  FIELD=TBLAMTB2,     ALIAS=E07,   USAGE=P6,       ACTUAL=Z5,      $
```

**Example:** **Variable OCCURS**

Consider the following COBOL input description:

```plaintext
01  TABLE-REC.
   02  TABLE-COUNT            PIC S9(2) COMP.
   02  TABLE-ENTRY
      OCCURS 1 TO 10 TIMES
      DEPENDING ON TABLE-COUNT.
   03  TABLE-AMT-A        PIC S9(5).
   03  TABLE-AMT-B        PIC S9(5).
```

The translation generates the following Master Files from this input when either Y or N is entered for Describe OCCURS as Segments:

```plaintext
FILE=OCCURSVY,                     SUFFIX=FIX,                      $
SEGNAME=TABLESEG,     SEGTYPE=S0,                                   $
  FIELD=TABLECOUNT,   ALIAS=E01,   USAGE=I3,       ACTUAL=I2,      $
SEGNAME=TABLESEG2,     SEGTYPE=S0,  PARENT=TABLESEG,  $
  OCCURS=TABLECOUNT,                                                  $
  GROUP=TABLEENTRY,     ALIAS=E02,   USAGE=A16,      ACTUAL=A10,     $
  FIELD=TABLEAMTA,      ALIAS=E03,   USAGE=P6,       ACTUAL=Z5,      $
  FIELD=TABLEAMTB,      ALIAS=E04,   USAGE=P6,       ACTUAL=Z5,      $
```
The fields to be reported from (TABLEAMTA and TABLEAMTB) are within the OCCURS segment. The number of table occurrences is determined automatically by the TABLECOUNT field.

**Example: Nested OCCURS**

Consider the following COBOL input description:

```cobol
01  TABLE-REC.
   02  TABLE-LEVEL-A OCCURS 2.
      03  TABLE-LEVEL-B OCCURS 3.
      04  TABLE-AMT               PIC S9(5) COMP-3.
```

The translation can generate the following two Master Files from this input, depending on the value entered for Describe OCCURS as Segments:

For a value of Y:

```plaintext
FILE=OCCURSNY, SUFFIX=FIX, $ 
SEGNAME=TABLESEG, SEGTYPE=S0, $ 
   GROUP=TABLEREC, ALIAS=E01, USAGE=A18, ACTUAL=A18, $ 
   FIELD=TABLESE2POSN, ALIAS=E02, USAGE=A18, ACTUAL=A18, $ 
SEGNAME=TABLESE2, SEGTYPE=S0, PARENT=TABLESEG, OCCURS=2, $ 
   POSITION=TABLESE2POSN, GROUP=TABLELEVELA, ALIAS=E03, USAGE=A9, ACTUAL=A9, $ 
   FIELD=TABLESE3POSN, ALIAS=E04, USAGE=A9, ACTUAL=A9, $ 
SEGNAME=TABLESE3, SEGTYPE=S0, PARENT=TABLESE2, OCCURS=3, $ 
   POSITION=TABLESE3POSN, GROUP=TABLELEVELB, ALIAS=E05, USAGE=A8, ACTUAL=A3, $ 
   FIELD=TABLEAMT, ALIAS=E06, USAGE=P6, ACTUAL=P3, $ 
```

The translation defines the nested table structure with nested segments. You need only refer to the final reporting field, TABLEAMT.
For a value of N:

```cobol
FILE=OCCURSNN,                     SUFFIX=FIX,                      $  
SEGNAME=TABLESEG,     SEGTYPE=S0,                                   $  
  GROUP=TABLEREC,   ALIAS=E01,   USAGE=A48,      ACTUAL=A18,     $  
  GROUP=TABLELEVELA1, ALIAS=E02,   USAGE=A24,      ACTUAL=A9,      $  
  FIELD=TABLEAMT11,  ALIAS=E03,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB1, ALIAS=E04,   USAGE=P6,       ACTUAL=P3,      $  
  FIELD=TABLEAMT12,  ALIAS=E05,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB2, ALIAS=E06,   USAGE=P6,       ACTUAL=P3,      $  
  FIELD=TABLEAMT13,  ALIAS=E07,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB3, ALIAS=E11,   USAGE=P6,       ACTUAL=P3,      $  
  FIELD=TABLEAMT14,  ALIAS=E12,   USAGE=P6,       ACTUAL=P3,      $  
  GROUP=TABLELEVELB4, ALIAS=E13,   USAGE=A8,       ACTUAL=A3,      $  
  FIELD=TABLEAMT15,  ALIAS=E14,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB5, ALIAS=E15,   USAGE=A8,       ACTUAL=A3,      $  
  FIELD=TABLEAMT16,  ALIAS=E16,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB6, ALIAS=E17,   USAGE=A8,       ACTUAL=A3,      $  
  FIELD=TABLEAMT17,  ALIAS=E18,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB7, ALIAS=E19,   USAGE=A8,       ACTUAL=A3,      $  
  FIELD=TABLEAMT18,  ALIAS=E20,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB8, ALIAS=E21,   USAGE=A8,       ACTUAL=A3,      $  
  FIELD=TABLEAMT19,  ALIAS=E22,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB9, ALIAS=E23,   USAGE=A8,       ACTUAL=A3,      $  
  FIELD=TABLEAMT20,  ALIAS=E24,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELA2, ALIAS=E25,   USAGE=A24,      ACTUAL=A9,      $  
  FIELD=TABLEAMT21,  ALIAS=E26,   USAGE=A8,       ACTUAL=A3,      $  
  GROUP=TABLELEVELB10, ALIAS=E27,  USAGE=A8,       ACTUAL=A3,     $  
  FIELD=TABLEAMT22,  ALIAS=E28,   USAGE=A8,       ACTUAL=A3,     $  
  GROUP=TABLELEVELB11, ALIAS=E29,  USAGE=A8,       ACTUAL=A3,     $  
  FIELD=TABLEAMT23,  ALIAS=E30,   USAGE=A8,       ACTUAL=A3,     $  
```

**ORDER Field**

**Example:**

```
ORDER Field Sequence With Nested OCCURS
```

If you wish to select specific occurrences for reporting, add an ORDER field to the Master File as the last entry of the OCCURS segment:

```cobol
FIELD=fieldname,    ALIAS=ORDER, USAGE=I4,       ACTUAL=I4, $  
```

The value for ALIAS must be ORDER, the value for ACTUAL must be I4, the field name is arbitrary, and the value for USAGE must be an integer (I) but can be of any length from 1 to 9. The ORDER field is automatically populated.
**Example:**  ORDER Field Sequence With Nested OCCURS

The following example adds the ORDER field SEQUENCE to the nested fixed OCCURS segments 2 and 3:

```
FILE=OCCURSNY,                     SUFFIX=FIX,                      $
SEGNAME=TABLESEG,     SEGTYPE=S0,                                   $
GROUP=TABLEREC,     ALIAS=E01,   USAGE=A18,      ACTUAL=A18,     $
FIELD=TABLESE2POSN, ALIAS=E02,   USAGE=A18,      ACTUAL=A18,     $
SEGNAME=TABLESE2,     SEGTYPE=S0,  PARENT=TABLESEG,           
OCCURS=2,             POSITION=TABLESE2POSN,                        $
GROUP=TABLELEVELA,  ALIAS=E03,   USAGE=A9,       ACTUAL=A9,      $
FIELD=TABLESE3POSN, ALIAS=E04,   USAGE=A9,       ACTUAL=A9,      $
FIELD=SEQUENCEA,    ALIAS=ORDER, USAGE=A9,       ACTUAL=A9,      $
SEGNAME=TABLESE3,     SEGTYPE=S0,  PARENT=TABLESE2,           
OCCURS=3,             POSITION=TABLESE3POSN,                        $
GROUP=TABLELEVELB,  ALIAS=E05,   USAGE=A8,       ACTUAL=A3,      $
FIELD=TABLEAMT,     ALIAS=E06,   USAGE=P6,       ACTUAL=P3,      $
FIELD=SEQUENCEB,    ALIAS=ORDER, USAGE=A9,       ACTUAL=A9,      $
```

**Zoned Numeric Field Usage**

**Example:**

Zoned Numeric Field Usage

A COBOL FD may describe alphanumeric characters as zoned decimal numeric data using the PICTURE 9(n) clause. This clause is commonly used for numeric string data on which no arithmetic operations is performed, such as phone numbers, identification numbers, and dates. You can describe these fields in packed numeric or alphanumeric USAGE format (enter the values P or A, respectively). The ACTUAL format is described as zoned (Z).

If you intend to use COBOL numeric display fields for summing or in mathematical operations, use the packed option. If you intend to use these elements for display only, use the alphanumeric option. Only simple numeric display elements of the format PICTURE 9(n) are subject to this feature. Signed elements (PICTURE S9(n)) and elements with decimal positions (PICTURE 9(n)V(m)) are always described as packed.
**Example: Zoned Numeric Field Usage**

Consider the following COBOL input description:

```
01 EMPL-REC.
   02 EMPL-SOC-SEC-NUM   PIC 9(8).
   02 EMPL-HIRE-DATE.
   03 EMPL-HIRE-YEAR    PIC 9(2).
   03 EMPL-HIRE-MONTH   PIC 9(2).
   03 EMPL-HIRE-DAY     PIC 9(2).
   02 EMPL-SICK-DAYS-ALLOWED PIC S9(2).
   02 EMPL-SICK-DAYS-TAKEN PIC 9(2).
   02 EMPL-YTD-HOURS-WORKED PIC 9(4)V9(2).
```

The translation can generate the following two Master Files from this input, depending on the value entered for Zoned Numeric Field Usage.

For a value of P:

```
FILE=ZONEDP,                     SUFFIX=FIX,                    $
SEGNAME=RECSEG,       SEGTYPE=S0,                                  $
   GROUP=REC,          ALIAS=E01,   USAGE=A56,      ACTUAL=A24,     $
   FIELD=SOCSECNUM,    ALIAS=E02,   USAGE=P8,       ACTUAL=Z2,      $
   GROUP=HIREDATE,     ALIAS=E03,   USAGE=A24,      ACTUAL=A6,      $
   FIELD=HIREYEAR,     ALIAS=E04,   USAGE=P2,       ACTUAL=Z2,      $
   FIELD=HIREMONTH,    ALIAS=E05,   USAGE=P2,       ACTUAL=Z2,      $
   FIELD=HIREDAY,      ALIAS=E06,   USAGE=P2,       ACTUAL=Z2,      $
   FIELD=SICKDAYSALLO, ALIAS=E07,   USAGE=P3,       ACTUAL=Z2,      $
   FIELD=SICKDAYSTAKE, ALIAS=E08,   USAGE=P2,       ACTUAL=Z2,      $
   FIELD=YTDHOURSWORK, ALIAS=E09,   USAGE=P7.2,     ACTUAL=Z6,      $
```

For a value of A:

```
FILE=ZONEDA,                     SUFFIX=FIX,                    $
SEGNAME=RECSEG,       SEGTYPE=S0,                                  $
   GROUP=REC,          ALIAS=E01,   USAGE=A32,      ACTUAL=A24,     $
   FIELD=SOCSECNUM,    ALIAS=E02,   USAGE=A8,       ACTUAL=Z2,      $
   GROUP=HIREDATE,     ALIAS=E03,   USAGE=A24,      ACTUAL=A6,      $
   FIELD=HIREYEAR,     ALIAS=E04,   USAGE=A2,       ACTUAL=Z2,      $
   FIELD=HIREMONTH,    ALIAS=E05,   USAGE=A2,       ACTUAL=Z2,      $
   FIELD=HIREDAY,      ALIAS=E06,   USAGE=A2,       ACTUAL=Z2,      $
   FIELD=SICKDAYSALLO, ALIAS=E07,   USAGE=P3,       ACTUAL=Z2,      $
   FIELD=SICKDAYSTAKE, ALIAS=E08,   USAGE=A2,       ACTUAL=Z2,      $
   FIELD=YTDHOURSWORK, ALIAS=E09,   USAGE=P7.2,     ACTUAL=Z6,      $
```

The two generated Master Files contains zoned decimal fields that are truly used in numeric and alphanumeric formats, but the translation cannot distinguish between the two cases. You must select the option most appropriate to your situation. You may edit the resulting Master File to change the formats to packed or alphanumeric as necessary. The USAGE length of any GROUP fields that contain these zoned fields must also be changed, according to the format conversion rules in General Format Conversion Notes on page 2788.
Numeric Field Edit Options

Example:
Numeric Field Edit Options

The COBOL FD translation automatically adds any edit options that you supply to all numeric fields in the generated Master File. Edit options affect how the numeric data is displayed. The options are as follows:

S - Suppresses printing of the digit zero for a field whose value is zero.
C - Includes commas where appropriate, for example, 1,234.
B - Brackets negative values, for example, (1234).
R - Credits negative values, for example, 1234 CR.
M - Displays a floating dollar sign with commas, for example, $1,234.
N - Displays a fixed dollar sign with commas, for example, $ 1,234.
L - Displays leading zeroes, for example, 001234.

You may enter up to five edit options. You may leave this option blank if you do not wish to edit numeric fields. Edit options may be entered in any order and combination except for the pairs SL, MN, and BR, which are mutually exclusive.

Example: Numeric Field Edit Options

Consider the following COBOL input description:

```
01  PAYROLL-REC.
   05  PAYROLL-NAME.
      10  PAYROLL-LAST-NAME  PIC X(20).
      10  PAYROLL-FIRST-NAME  PIC X(10).
   05  PAYROLL-AMT-FIELDS.
      10  PAYROLL-AMT-PREV-YR  PIC S9(7)V99 COMP-3.
```
The translation generates the following Master Files from this input when MB is entered for Numeric Field Edit Options:

```
FILE=EDITOPT,                      SUFFIX=FIX,                      $
SEGNAME=RECSEG,                  SEGTYPE=S0,                                      $
   GROUP=REC,     ALIAS=E01,   USAGE=A46,      ACTUAL=A40,     $
   GROUP=NAME,    ALIAS=E02,   USAGE=A30,      ACTUAL=A30,     $
   FIELD=LASTNAME, ALIAS=E03,   USAGE=A20,      ACTUAL=A20,     $
   FIELD=FIRSTNAME, ALIAS=E04,   USAGE=A10,      ACTUAL=A10,     $
   GROUP=AMTFIELDS, ALIAS=E05,   USAGE=A16,      ACTUAL=A10,     $
   FIELD=AMTCURRYR, ALIAS=E06,   USAGE=P11.2MB,  ACTUAL=P5,      $
   FIELD=AMTPREVYR, ALIAS=E07,   USAGE=P11.2MB,  ACTUAL=P5,      $
```

### Field Name Information

The translation generates field names in the Master File from COBOL field names using the following:

1. The Skip 'n' Hyphens option removes characters from the left, up to and including the nth hyphen (depending on the value of n you entered on the menu). It then either removes all remaining hyphens or replaces them with underscores, depending on the setting of the menu option Remove Hyphens or Use Underbars. Finally, if the Field Name Length option has been set to 12, only the 12 leftmost characters are used.

2. If the name duplicates a previously-generated field name, a qualifier is added to make it unique. For example, given the following COBOL structure

```cobol
02  EMPL-PORTION.
   03  SOC-SEC-NUM   PIC 9(9).
02  MGR-PORTION.
   03  SOC-SEC-NUM   PIC 9(9).
```

SOCSECNUM is generated from the first elementary field name and SOCSECNUM2 from the second elementary field name.
The following table illustrates the results of the possible combinations of menu options that control field name generation.

<table>
<thead>
<tr>
<th>COBOL Field Name: PAYROLL-REC-IN-FICA</th>
<th>Field Name Length</th>
<th>Remove Hyphens or Use Underbars</th>
<th>Skip 'n' Hyphens</th>
<th>Generated Field Name</th>
</tr>
</thead>
<tbody>
<tr>

**General Format Conversion Notes**

Format conversion is the process of defining the ACTUAL and USAGE formats based on the COBOL format. The translation performs the conversion as described in the following table:

<table>
<thead>
<tr>
<th>COBOL Format</th>
<th>ACTUAL</th>
<th>USAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>PICTURE X(n)</td>
<td>An</td>
<td>An</td>
</tr>
<tr>
<td>PICTURE 9(n)</td>
<td>Zn (packed option)</td>
<td>Pn (packed option)</td>
</tr>
<tr>
<td>COBOL Format</td>
<td>ACTUAL</td>
<td>USAGE</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>PICTURE 9(n)</td>
<td>An (alpha option)</td>
<td>An (alpha option)</td>
</tr>
<tr>
<td>PICTURE S9(n)</td>
<td>Zn</td>
<td>P(n+1)</td>
</tr>
<tr>
<td>PICTURE 9(n)V9(m)</td>
<td>Zn+m</td>
<td>P(n+m+1.m)</td>
</tr>
<tr>
<td>PICTURE S9(n)V9(m)</td>
<td>Zn+m</td>
<td>P(n+m+2.m)</td>
</tr>
<tr>
<td>PICTURE 9(n) COMP (1 # n # 4)</td>
<td>I2</td>
<td>I9</td>
</tr>
<tr>
<td>PICTURE 9(n) COMP (5 # n # 9)</td>
<td>I4</td>
<td>I9</td>
</tr>
<tr>
<td>PICTURE 9(n) COMP (n &gt; 9)</td>
<td>A8</td>
<td>A8</td>
</tr>
<tr>
<td>COMP-1</td>
<td>F4</td>
<td>F8</td>
</tr>
<tr>
<td>COMP-2</td>
<td>D8</td>
<td>D15</td>
</tr>
<tr>
<td>PICTURE 9(n) COMP-3</td>
<td>P(n+2/2)</td>
<td>P(n)</td>
</tr>
<tr>
<td>PICTURE S9(n) COMP-3</td>
<td>P(n+2/2)</td>
<td>P(n+1)</td>
</tr>
<tr>
<td>PICTURE 9(n)V9(m) COMP-3</td>
<td>P(n+m+2/2)</td>
<td>P(n+m+1.m)</td>
</tr>
<tr>
<td>PICTURE S9(n)V9(m) COMP-3</td>
<td>P(n+m+2/2)</td>
<td>P(n+m+2.m)</td>
</tr>
</tbody>
</table>

The format conversions are subject to the following limitations:

- Alphanumeric fields are limited to 256 characters. Elementary fields that exceed 256 characters are truncated to 256 characters and have filler fields inserted to provide for the total length. Group fields that exceed 256 characters are commented.

- Unsigned zoned fields that exclude a decimal point are described with a USAGE of packed (P) or alphanumeric (A), depending on the value entered for the Zoned Numeric Field Usage option.

- COMP-4 binary fields are described the same as COMP fields.

- Binary fields that exceed 9 digits in the picture clause are described with ACTUAL format A8 and USAGE format A8.
The maximum length of the packed USAGE format depends on the software release that uses the generated Master File. For releases that support long packed fields (16 or more digits), the maximum ACTUAL length is 16 bytes and the maximum USAGE length is 31 digits (or 32 characters including a decimal point and sign). For earlier releases, the maximum ACTUAL length is 8 bytes and the maximum USAGE length is 15 total digits, including decimal and sign. The number of decimal places is limited to one fewer than the total USAGE length.

In general, the USAGE length of packed fields is calculated as the sum of the digits to the left of the decimal (n), the number of decimal positions (m), one for the leading minus sign if present (S), and one for the decimal (V) if present.

The ACTUAL and USAGE formats for GROUP fields are always alphanumeric (A). The ACTUAL length is the sum of the ACTUAL lengths of its components. The USAGE length is the sum of the following:

- The USAGE lengths of all the alphanumeric (A) components.
- 16 for each long packed (P) component.
- 8 for each short packed (P) and double precision (D) component.
- 4 for each integer (I) and floating point (F) component.

### Multiple Records as Input

**Example:**

Multiple Records as Input

The translation generates a new segment for each COBOL record description (01-level field) it receives as input. When multiple records are present, an additional DUMMY segment is created that is used as the common parent for the record descriptions. Whenever you submit more than one 01-level record as input, you must manually add RECTYPE fields to identify the different record types.
Example: Multiple Records as Input

Consider the following COBOL input description:

```cobol
01  HDR-REC.
   02  HDR-KEY            PIC X(1).
       88 HDR-VALUE       VALUE 'H'.
   02  HDR-DATA           PIC X(10).
01  DET-REC.
   02  DET-KEY            PIC X(1).
       88 DTL-VALUE       VALUE 'D'.
   02  DTL-DATA           PIC X(10).
```

From this input, the following Master File with multiple segments is created:

```cobol
FILE=MULT01, $
   SUFFIX=FIX, $
   SEGNAME=DUMMY, SEGTYPE=S0, $
   FIELD=, ALIAS=, USAGE=A1, ACTUAL=A1, $
   SEGNAME=HDRRESEG, SEGTYPE=S0, PARENT=DUMMY, $
   GROUP=HDRREC, ALIAS=E01, USAGE=A11, ACTUAL=A11, $
   FIELD=HDRKEY, ALIAS=E02, USAGE=A1, ACTUAL=A1, $
   $  HDRVALUE, VALUE 'H'. $
   FIELD=HDRDATA, ALIAS=E03, USAGE=A10, ACTUAL=A10, $
   SEGNAME=DETRESEG, SEGTYPE=S0, PARENT=DUMMY, $
   GROUP=DETREC, ALIAS=E04, USAGE=A11, ACTUAL=A11, $
   FIELD=DETKEY, ALIAS=E05, USAGE=A1, ACTUAL=A1, $
   $  DTLVALUE, VALUE 'D'. $
   FIELD=DTLDATA, ALIAS=E06, USAGE=A10, ACTUAL=A10, $
```

After editing to add the RECTYPE information, the completed Master File is:

```cobol
FILE=MULT01, $
   SUFFIX=FIX, $
   SEGNAME=DUMMY, SEGTYPE=S0, $
   FIELD=, ALIAS=, USAGE=A1, ACTUAL=A1, $
   SEGNAME=HDRRESEG, SEGTYPE=S0, PARENT=DUMMY, $
   GROUP=HDRREC, ALIAS=E01, USAGE=A11, ACTUAL=A11, $
   FIELD=RECTYPE, ALIAS=H, USAGE=A1, ACTUAL=A1, $
   $  HDRVALUE, VALUE 'H'. $
   FIELD=HDRDATA, ALIAS=E03, USAGE=A10, ACTUAL=A10, $
   SEGNAME=DETRESEG, SEGTYPE=S0, PARENT=DUMMY, $
   GROUP=DETREC, ALIAS=E04, USAGE=A11, ACTUAL=A11, $
   FIELD=RECTYPE, ALIAS=D, USAGE=A1, ACTUAL=A1, $
   $  DTLVALUE, VALUE 'D'. $
   FIELD=DTLDATA, ALIAS=E06, USAGE=A10, ACTUAL=A10, $
```
Maximum Number of Fields

**Example:**

Maximum Number of Fields

Each 01-level record input can contain up to 4,000 fields. Any number of 01-level entries can be used as input to the translation, as long as no individual record exceeds this limit. Each occurrence of an OCCURS structure counts in this limit. If the limit is exceeded, an error message is printed and program execution stops. Note that this limitation applies to the translation and not the Master File generated.

**Example:**

Consider the following COBOL input description:

```
01  REC1.
   02  FLD1 OCCURS 5000 TIMES PIC X(1).
```

This input generates the following message:

```
FR011E - INTERNAL TABLE OVERFLOW
```

To bypass this limitation, edit the COBOL FD and temporarily reduce the total number of OCCURS. After execution, edit the Master File and restore the original number of occurrences.

Consider the following COBOL input description:

```
01  REC1.
   02  FLD1 OCCURS 2000 TIMES PIC X(1).
01  REC2.
   02  FLD2 OCCURS 2000 TIMES PIC X(1).
```
The following Master File, with multiple segments, is created from this input:

```
FILE=MAXRECS,                        SUFFIX=FIX,                        $
SEGNAME=DUMMY,        SEGTYPE=S0,     $ 
FIELD=,             ALIAS=,      USAGE=A1,       ACTUAL=A1,     $ 
SEGNAME=REC1SEG,      SEGTYPE=S0,  PARENT=DUMMY,                    $ 
$  GROUP=REC1,         ALIAS=E01,   USAGE=A2000,    ACTUAL=A2000,   $ 
FIELD=FLD1SEGPOSN,  ALIAS=E02,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E03,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E04,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E05,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E06,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E07,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E08,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E09,   USAGE=A208,     ACTUAL=A208,    $ 
SEGNAME=FLD1SEG,      SEGTYPE=S0,  PARENT=REC1SEG, 
OCCURS=2000,          POSITION=FLD1SEGPOSN,                         $ 
FIELD=FLD1,         ALIAS=E10,   USAGE=A1,       ACTUAL=A1,      $ 
SEGNAME=REC2SEG,      SEGTYPE=S0,  PARENT=DUMMY,                    $ 
$  GROUP=REC2,         ALIAS=E11,   USAGE=A2000,    ACTUAL=A2000,   $ 
FIELD=FLD2SEGPOSN,  ALIAS=E12,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E13,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E14,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E15,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E16,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E17,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E18,   USAGE=A256,     ACTUAL=A256,    $ 
FIELD=FILLER,       ALIAS=E19,   USAGE=A208,     ACTUAL=A208,    $ 
SEGNAME=FLD2SEG,      SEGTYPE=S0,  PARENT=REC2SEG, 
OCCURS=2000,          POSITION=FLD2SEGPOSN,                         $ 
FIELD=FLD2,         ALIAS=E20,   USAGE=A1,       ACTUAL=A1,      $ 
```

This description does not exceed the 4,000 field limit because each 01-level has fewer than 4,000 fields.

**Year 2000**

Because a COBOL FD cannot describe fields as dates, the translation cannot reliably determine which fields are dates and apply date formats to them. However, you can edit Master Files generated during synonym creation to add date formats and date defaults. These are respected in Information Builders software designed to take advantage of them.
COBOL FD Syntax Requirements

The COBOL FD translation requires a syntactically correct COBOL file description as input. While scanning the COBOL file description during synonym creation, a number of syntax checks are performed. If any of the COBOL statements are invalid, debugging messages are displayed, the program stops executing, and a Master File is not generated. Although the syntax check can identify a variety of errors, you should specify only valid COBOL file descriptions that compile successfully.

Reference: COBOL FD Syntax Guidelines

At a minimum, a valid COBOL file description must follow these guidelines:

- Level-numbers must be a one-digit or two-digit integer. Values can be 1 through 49, 66, 77, or 88.
- Level-numbers 01 and 77 must begin in Columns 8 through 11; all other level-numbers may begin in Columns 8 through 72.
- Comment lines are identified with an asterisk (*) in Column 7.
- Continuation lines are identified with a hyphen (-) in Column 7.
- The COBOL file description starts with a level-number 01 column and ends with the last column described.
- The COBOL field names are in uppercase characters.
- Other COBOL instructions are not permitted as input.
- Embedded tabs and blank lines are not permitted as input.
- Up to nine lines are supported in a multilevel value clause.
  Only one level is commented in the Master File.
The ZCOMP Exit applies to VSAM, ISAM, CISAM, RMS and other SAM type data structures, and to certain FIX structures.

Three functions plus a main entry point comprise the compression exit, collectively known as the ZCOMP Exit. The main entry point is ZCOMP which exports:

- ZCOMPO for initial housekeeping.
- ZCOMP1 for the actual processing. It is designed so customers can access and decrypt coded fields, expand compressed records, and accomplish other specified data manipulations.
- ZCOMP2 is called to perform clean-up when the session is over.

Anchor storage is passed to ZCOMPO, ZCOMP1 and ZCOMP2 to maintain persistence and reentrancy.

The ZCOMP reference code is supplied, however, the actual DLL is expected to be user-written, and maintained to fit the specific need. The exit must be compiled and linked in accordance with standard user-written exit procedures.

There are no special Master File coding requirements to use ZCOMP. The SUFFIX value can be VSAM (for KSDS or ESDS files), CISAM, RMS, FIX (for sequential files), or PRIVATE (for file access through the GETPRV user exit).
Invoking the ZCOMP Exit

The ZCOMP Exit DLL may be written in C, BAL, or any 3GL languages that follows the parameter passing conventions used in the reference samples and are compiled and linked as a proper DLL. The generated DLL must have an entry point that matches the physical name of the DLL. The default DLL name is ZCOMP.

After you write a ZCOMP user exit, depending upon the platform, you compile and link it as follows:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Compile/Link Mechanism</th>
</tr>
</thead>
<tbody>
<tr>
<td>USS, UNIX, Windows, IBM i, and OpenVMS</td>
<td>GENCPGM. (See the Stored Procedures Reference manual for related information.)</td>
</tr>
<tr>
<td>z/OS</td>
<td>Build the DLL or link with VVSET using FOCCTL.DATA(GENFSAM) JCL</td>
</tr>
<tr>
<td>VM/ESA</td>
<td>Build the DLL or link with VVSET using GENFSAM EXEC</td>
</tr>
</tbody>
</table>

**Note:**

- z/OS and VM/ESA linking with VVSET is an obsolete technique that is only supported for backward compatibility.
- The GENFSAM JCL and EXEC for mainframe are designed to link to both the ZCOMP and the GETPRV user exits at the same time. If you are only implementing one of these exits, the VM EXEC generates the correct linkage to the routine required, whereas the z/OS JCL does not. In the latter case, you must comment out the INCLUDE OBJECT statements in the GENFSAM member.
- On z/OS and VM/ESA, the ZCOMP can be linked as re-entrant if you plan to use the USERWD parameter. For information about GENCPGM usage, see the Stored Procedures Reference manual.

The point in the process at which the ZCOMP Exit DLL is loaded depends on the platform and on whether linking is done with VVSET:

- Platforms using exits linked into VVSET receive the default ZCOMP exit load when a user session starts; it is unloaded on exit.
Platforms using the exit as a DLL load only in response to an explicit request, such as SELECT or TABLE, which must be issued prior to data requests. The commands specify the data source, as in the following illustrations:

```
ENGINE VSAMX SET ZCOMP dllname
ENGINE CISAM SET ZCOMP dllname
ENGINE RMS SET ZCOMP dllname
```

Users can dynamically change the DLL during the session as needed. The current DLL unloads upon the change to the DLL in use and upon a user session exit.

To force an explicit DLL unload, use the SET command with a non-existent DLL name. The DLL location is defined by the IBICPG environment variable. The main DLL entry point function (which is required to be the same as the DLL name) provides the adapter with the addresses of the ZCOMPO, ZCOMP1 and ZCOMP2 functions.

The VSAM engine is used to process SUFFIX=PRIVATE and multi-segment SUFFIX=FIX files, as well as SUFFIX=VSAM files. The following command is used for FIX and PRIVATE:

```
ENGINE VSAMX SET ZCOMP
```

What Happens When ZCOMP is LOADED?

**Example:**

Passing Records

ZCOMP C Source File (zcomp.c)

ZCOMP Header File (zcomp.h)

**Reference:**

ZCOMP1 BAL Parameter List

An adapter (as defined by the SUFFIX= value in the Master File) reads records. Upon each successful read, if the ZCOMP Exit DLL is loaded the adapter calls ZCOMP1 to do manipulations, such as data decompression.

The ZCOMP1 logic is responsible for determining what to do based upon the parameter information it receives. Typically, the DDNAME value is used to determine if the associated data source needs to be decompressed or otherwise manipulated.

- If neither decompression nor manipulation is needed, the user exit typically moves A(IRECLEN) to A(ORECLEN) and A(A(IREC)) to A(A(OREC)) and returns to the adapter with a zero A(STATCODE), thus acting like a pass through. For related information, see ZCOMP1 BAL Parameter List on page 2802.
If decompression or another type of manipulation is required, it is the responsibility of the user exit to perform these tasks.

**Example:** Passing Records

Note that the following example simply passes records since decompression, or another type of manipulation, is application-specific.

After the user exit completes its processing, it returns either A(ORECLLEN), A(A(OREC)), and a zero status code, or a non-zero status code that generates the following message:

(FOC1150) ZCOMP DECOMPRESS ERROR: status

This error terminates a TABLE request.

**Example:** ZCOMP C Source File (zcomp.c)

```c

 *-----------------------------------------------*/

/*
 This zcomp sample is an arbitrary example in which we simply move an uncompressed input buffer and size to the output buffer and size. Effectively, this is a pass through of operation just passing the buffer along; no real decompression occurs in the sample. If this was coded as a real application, actual decompression would be done using a third party compression/decompression routine linked in the sample for the purpose of actual use in the ZCOMP1 exit.

 Typically this procedure would be built via gencpgm and IBICPG set. Once the sample exit has been built, it may be exercised to observe behavior using the zcomp.fex procedure.
 */
```

What Happens When ZCOMP is LOADED?
/* stdio needed for printf() lines, your code may not need stdio */
#include <stdio.h>
#include "zcomp.h"

void zcomp0 {
    long   *status     /* out: status, 0=OK                 */
    ,char   *filename   /* in : ddname                       */
    ,char   *userid     /* in : userid or jobname            */
    ,long   *reserv1    /* reserved: NOT TO BE USED BY EXIT  */
    ,char   **reserv2    /* reserved: NOT TO BE USED BY EXIT  */
    ,long   *reserv3    /* reserved: NOT TO BE USED BY EXIT  */
    ,char   **reserv4    /* reserved: NOT TO BE USED BY EXIT  */
    ,long   *user_wk    /* i/o : work area for the user exit */

    {
        /* Arbitrary to show behavior; would not be coded in a real application */
        printf("ZCOMP0 called to do initial housekeeping\n");
        *status = 0;
    }
}

void zcomp1 {
    long   *status     /* out: status, 0=OK                 */
    ,char   *filename   /* in : ddname                       */
    ,char   *userid     /* in : userid or jobname              */
    ,long   *inlen      /* in : length of original record      */
    ,char   **inabuf     /* in : input record buffer            */
    ,long   *outlen     /* out : length of decoded record      */
    ,char   **outabuf    /* out : decoded output record buffer  */
    ,long   *user_wk    /* i/o : work area for the user exit */

    {
        /* Arbitrary to show behavior; would not be coded in a real application */
        printf("ZCOMP1 called to do the actual processing\n");
        /* In a real application decompression steps would normally be done here */
        *outlen = *inlen;
        *outabuf = *inabuf;
        *status = 0;
    }
}

void zcomp2 {
    long   *user_wk    /* I/O work area for the user exit */

    {
        /* Arbitrary to show behavior; would not be coded in a real application */
        printf("ZCOMP2 called to perform clean-up, session is over\n");
    }
}
What Happens When ZCOMP is LOADED?

```c
void zcomp(p_zcompep pzc)
{
    /* Arbitrary to show behavior; would not be coded in a real application */
    printf("ZCOMP called to initialize entry points for ZCOMP0, ZCOMP1 and ZCOMP2\n");
    pzc->zcomp0 = zcomp0;
    pzc->zcomp1 = zcomp1;
    pzc->zcomp2 = zcomp2;
}
```

Example: ZCOMP Header File (zcomp.h)

```c
#ifndef ZCOMP_H
#define ZCOMP_H 1

#include "fostda.h"

/*-perform the set-up in the user exit
 */

typedef void t_zcomp0 (long *status, char *filename, char *userid, long *reserv1, char **reserv2, long *reserv3, char **reserv4, long *user_wk);
#endif /* ZCOMP_H */
```

What Happens When ZCOMP is LOADED?

- **ZCOMP**
  - **API**
    - **Purpose**: API to process compressed records
    - **Interface**: Read by the VSAM interface
    - **Applicability**: Applicable to all files processed by VSAM
    - **Source Control Tag**: @MFSM_NOPROLOG@

The **ZCOMP** header file (zcomp.h) defines the ZCOMP0 function with the following signature:

```c
typedef void t_zcomp0 (long *status, char *filename, char *userid, long *reserv1, char **reserv2, long *reserv3, char **reserv4, long *user_wk);
```

This function is typically used to set up the user exit when ZCOMP is loaded.
/*
   decompress a record and return the address of the new record and its length. The routine is responsible for allocating a buffer for the decompressed record.
*/
typedef void  t_zcomp1 (long       *status     /* out: status = 0 if OK*/,
               char       *filename   /* in : ddname            */,
               char       *userid     /* in : userid or jobname */,
               long       *inlen      /* in : length of original rec */,
               char      **inabuf     /* in : a' input record */,
               long       *outlen     /* out : length of decoded rec */,
               char      **outabuf    /* out : a' decoded record */,
               long       *user_wk    /* i/o : work area for the user exit */);

/*
   -deallocate buffer used by zcomp1
called at the end of focus session.
*/
typedef void  t_zcomp2 (long       *user_wk    /* i/o : work area for the user exit */);

/*
   -definition of EPs exported by the dynamic zcomp exit
*/
typedef struct s_zcompep
{
    t_zcomp0 *zcomp0; /* p' to zcomp0 */
    t_zcomp1 *zcomp1; /* p' to zcomp1 */
    t_zcomp2 *zcomp2; /* p' to zcomp2 */
} t_zcompep, *p_zcompep;
What Happens When ZCOMP is LOADED?

/*
   Main and only one entry point in the ZCOMP module (dll)
*/
#ifdef __cplusplus
extern "C" {
#endif
typedef void  t_zcomp(p_zcompep pzc);
t_zcomp zcomp;
#ifdef __cplusplus
} /* extern "C" */
#endif /* __cplusplus */
#endif

<td>A(USERWD)**</td>
<td>Pointer to full word</td>
<td>4-byte integer</td>
</tr>
</tbody>
</table>

* The user supplies these parameters.

** This parameter can be used to anchor user storage for re-entrant processing.
Note:

- Never modify the original pointers, only the pointers or values that they point to.
- Upon entry to ZCOMP1, the ORECLEN and OREC parameters are NULL. It is the responsibility of the user to fill these in correctly.
- While processing the end of session, a call is placed to the ZCOMP2 entry point, which enables the user to do any other global cleanup that is required.
- The parameters returned by ZCOMP1 are not validated. It is the responsibility of the user routine to ensure that valid addresses and lengths are returned to the caller from ZCOMP1.
- Unpredictable results occur if incorrect parameters are passed back from the routine.
What Happens When ZCOMP is LOADED?
The Dynamic Private User Exit is an API that enables you to build and integrate a custom 3GL dynamic load library (DLL) routine to access data sources for which no standard adapter is available. This technique provides a mechanism by which companies using proprietary (or obscure) data sources can take advantage of WebFOCUS data access.

The terms GETPRV and SUFFIX=PRIVATE are often used to refer to this exit.

While reference code and build instructions for the exit are supplied as part of the GETPRV exit, users are expected to write and maintain the actual DLL to fit specific application needs, and compile and link the exit in accordance with the standard procedures for designing and building user written exits, as described in the Stored Procedures Reference manual.

To facilitate troubleshooting, customers (or VARs) are responsible for following good practices in coding their applications. If a problem is encountered it should be reproducible through small representative modifications to the sample. Since specific application code may contain proprietary data or methods that slow down the resolution process with unnecessary complexity, this method should be used to provide reproductions of all problems.
FOCSAM and the GETPRV User Exit

In this section:
- General Features of the GETPRV Exit
- Functional Requirements for Using the GETPRV Exit

How to:
- Use the Dynamic Private Exit User Exit

FOCSAM is the underlying logic for accessing keyed and sequential data sources within Information Builders products using a variety of low-level physical retrieval modules. FOCSAM contains a user exit that can be invoked as an alternative to the standard low-level retrieval routines that are part of FOCSAM. The exit makes it possible to combine user-written code (as a DLL) devoid of any dependence on the internal structures used within IBI products with the logical retrieval functions of FOCSAM, such as record selection logic, treatment of missing records in multi-record files, JOINS between various types of files, etc.

An Access File with a MODNAME= value determines the specific physical DLL loadable library to be used for a given table. The DLL itself must have a matching entry point by the same name as dictated by IBI standards for user written subroutines. The DLL must be physically in the EDACONF user directory, or the IBICPG environment variable must be set to indicate an alternate (directory) location. Any additional entry points within the same module may also be accessed, however, if other modules with additional entry points are needed the Private User Exit module must include "loader" logic to make the entry points available. (Note that these are the same rules used for all customers writing loadable DLL subroutines, as described in the Store Procedures Reference, which you can consult for the finer points of physically building a proper DLL.)

Procedure:  How to Use the Dynamic Private Exit User Exit

This is an overview of the steps for using the Dynamic Private User Exit:

1. Determine a record layout for the interaction between FOCSAM, the DLL, and any required keys. From the FOCSAM perspective this is the metadata layout within a given Master File. From the DLL perspective this is the structure of the record data being returned within one of the API pointers.

2. Create a Master File with metadata that matches the chosen record layout.

3. Create an Access File that specifies the DLL that will be used to access and return the record data.

4. Design and create the DLL that will perform the data access and return the record data.
5. Set the IBICPG environment variable to indicate the (directory) location of the DLL before server start up, or place the DLL in the EDACONF user directory.

6. Access data as if it were just another table (although the actual specifics of the metadata and DLL are more involved).

**General Features of the GETPRV Exit**

The general features of the exit are:

- The CONTEXT parameter, which supports reentrancy, reduces storage requirements, and enhances invocation performance.

- Support for multiple concurrent exit processors provided through an Access File where a specific user exit module can be named on a per Master File basis.

- Dynamic invocation of the user exit at execution time, without the need to recompile or re-link between major releases.

  **Note:** Since the exposed parts of the API are stable, the need for application code changes, re-compilation, or re-linking is unlikely between major releases. However, IBI reserves the right to make such changes and customers using the exits should safeguard their source code so that it will be available should such changes be required or should the application need to move to a new platform.

- Initialization and shutdown calls that allow the exit to perform initial and final housekeeping.

- Control and Read options:
  - Control options: (O) OPEN file, (R) OPEN request (position), (C) CLOSE, and (F) FIN (FOCUS FIN or WebFOCUS Agent Exit)
  - Read options: (S) Sequential Read, (G) Generic (GE) Read, and (E) Direct (EQ) Read options.

- Maintain multiple positions on the same file for recursive Joins.

**Functional Requirements for Using the GETPRV Exit**

Functionally, the exit is a substitute for retrieval calls typically used against key-sequenced VSAM data sources or any data source that can be represented as such a file. The exit need not deal with intra-record structures represented by OCCURS phrases, nor with the translation of FOCUS IF/WHERE conditions into lower-level criteria. Both of these functions are performed by the driving logic within FOCUSAM.
The user-written code must conform to the following rules:

- The code must be able to obtain and return a record, given a full value of the key. The key is presumed to be unique (E Direct (EQ) Read) and only one access is attempted (no successive reads).

- The code must be able to obtain and return a record greater than or equal to a given value of the full or partial key (G Generic (GE) Read) for initial positioning and retrieval purposes. After the initial retrieval, access switches to a sequential read until a change in key is detected and the position/retrieve (generic read) logic is repeated for any successive keys (for example, IF COUNTRY EQ ENGLAND OR ITALY) else ends retrieval (CLOSE). It is assumed the records being access and retrieved are in sort order to allow proper positioning and detection of key changes. If the exit application code uses an API to do retrieval specifics, sort order specifics may be masked or irrelevant, but the need for sort order retrieval becomes obvious when used in the context of a plain text file such as used in the reference sample.

- The code must be able to obtain the next logical record, starting from the current position in the file (S Sequential Read). Successive sequential reads must return records in ascending sequence (bit by bit). No key or non-key information is passed except for subsequent sequential reads after a Generic (GE) Read on a secondary key. For simplicity (but not efficiency), the passed key information can also be ignored and the record returned as FOCSAM will be applying screening conditions also.

- Direct and Generic Reads that retrieve records must establish the starting position in the file for subsequent sequential reads. Direct reads that fail to retrieve the requested records need not establish these positions as only the initial request is attempted.

- For the open file request (O), the code must logically or physically open the file.

- If the logical end-of-file is reached as a result of a sequential read, an end-of-file signal must be returned by setting the record return length to zero. Subsequent sequential reads must return end-of-file signals rather than error indications, for example, when processing a JOIN. Error condition handling variable should not be used to indicate end-of-file.

- A close function must be provided that will result in the release of all resources and loss of position in the file, so that subsequent open requests will succeed.

- Successive close calls must be innocuous. For example, they must be prepared to handle conditions such as a close of a file that is already closed, without generating error conditions.

- A unique area may be obtained and maintained using the CONTEXT parameters on a per DDNAME basis.

- The code must be serially reusable and re-entrant. This is the norm for modern compilers and linkers, but on MVS this would be linking as AMODE 31.
Physical Implementation of the GETPRV Exit

The GETPRV exit is linked and called as a separate dynamically loadable module in compliance with the standard instructions for subroutine DLL construction and access. The process can be summarized as follows:

- Write the set EDAHOME program.
- Build and compile the 3-GL application with GENCPGM.
- Set IBICPG to the name of the directory where the application was built.
- Start the Server and issue an SQL or TABLE request.

Once the program is working properly, only the last two steps are necessary: set IBICPG and start the Server.

For details about subroutine DLL construction and use of the GENCPGM program, see the Stored Procedures Reference manual.

Only READ features of FOCSAM are supported.

Master File for Data Access With GETPRV

The Master File and attributes for data to be accessed using the GETPRV exit are the same as the attributes for any other FOCSAM data source, except that the SUFFIX value must be PRIVATE (no other value will invoke the exit), and a primary key must be specified as a GROUP with an ALIAS=KEY value. For example,

```
FILE=filename, SUFFIX=PRIVATE, 
SEGNAME=ROOT, SEGTYPE=S0, 
GROUP=keyname, ALIAS=KEY, USAGE=xx, ACTUAL=xx, 
FIELD=fieldname1, ALIAS=aliasname1, USAGE=xx, ACTUAL=xx, 
FIELD=fieldname2, ALIAS=aliasname2, USAGE=xx, ACTUAL=xx, 
```

Secondary keys are typically set up as follows:

```
FILE=filename, SUFFIX=PRIVATE, 
SEGNAME=ROOT, SEGTYPE=S0, 
GROUP=keyname, ALIAS=KEY, USAGE=xx, ACTUAL=xx, 
FIELD=fieldname1, ALIAS=aliasname1, USAGE=xx, ACTUAL=xx, 
FIELD=fieldname2, ALIAS=aliasname2, USAGE=xx, ACTUAL=xx, 
FIELD=fieldname2, ALIAS=KEY1, USAGE=xx, ACTUAL=xx, INDEX=I, 
FIELD=fieldname2, ALIAS=KEY2, USAGE=xx, ACTUAL=xx, INDEX=I, 
```
They may also be set up as follows:

```plaintext
FILE=filename, SUFFIX=PRIVATE, $
SEGNAME=ROOT, SEGTYPE=S0, $
GROUP=keyname, ALIAS=KEY, USAGE=xx, ACTUAL=xx, $
FIELD=fieldname1, ALIAS=aliasname1, USAGE=xx, ACTUAL=xx, $
FIELD=fieldname2, ALIAS=aliasname2, USAGE=xx, ACTUAL=xx, $
GROUP=keyname, ALIAS=KEY1, USAGE=xx, ACTUAL=xx, INDEX=I, $
FIELD=fieldname2, ALIAS=aliasname3, USAGE=xx, ACTUAL=xx, $
GROUP=keyname, ALIAS=KEY2, USAGE=xx, ACTUAL=xx, INDEX=I, $
FIELD=fieldname2, ALIAS=aliasname4, USAGE=xx, ACTUAL=xx, $
```

All standard rules for keys and discontiguous keys as described in the standard manuals for describing keyed sequential sources apply to the use of SUFFIX=PRIVATE and should also be consulted.

To reference a table, you must specify the physical name of the Master File (for example, mytable.mas) and it must be located in an application directory on the server application path. On MVS configurations using PDS for storing application files, the Master File must be in the PDS allocated to the DDNAME MASTER or be in a PDS for a given applications Master Files.

### Access File for Data Access With GETPRV

An Access File is required. It provides the actual physical name of the private exit by specifying a MODNAME value. On platforms like UNIX, which use DLLs naming conventions such as libxxxx.so. The xxxx portion is the value to specify as the MODNAME. For example,

```plaintext
MODNAME=pgmname, $
```

To reference a table, you must specify the physical name of the Access File (for example, mytable.acx) and it must be located in an application directory on the server’s application path. On MVS configurations using PDS for storing application files (where there are no file extensions), the Access File must be in the PDS allocated to the DDNAME ACCESS or be in a PDS for a given applications Access Files.
Calling Parameters and Work Areas

**Example:**

Sample C Header File Implementation for Calling and Work Area Control Block Parameters

Sample for SUFFIX=PRIVATE (getprv.c)

**Reference:**

Calling Parameters

Work Area Control Block Parameters

A user-coded retrieval routine must be written as a standalone DLL program. There are few limitations to the program other than standard C rules and a program name length of 8. It is advisable to write the program in a language that fully supports dynamic memory allocation, such as ASSEMBLER or C. Languages like COBOL can also be used, but with certain limitations in the ability to access extended parameters and set permanent address memory on some platforms.

Note that non-char parameter sizes are stated in terms of longs and pointers: 4 bytes each for 32-bit applications and 8 bytes each for 64-bit applications.

The basic function of a user-coded routine is to provide calling parameters for opening, positioning, reading, and closing in order to populate work areas with records to be passed back. For details, see Calling Parameters on page 2811 and Work Area Control Block Parameters on page 2813. A sample is also provided for your use (see Sample C Header File Implementation for Calling and Work Area Control Block Parameters on page 2816).

**Reference:**  Calling Parameters

The parameter list is as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCHAR</td>
<td>Long, posted by the exit; a positive number indicates the length in bytes of the record obtained and being returned; a zero indicates no record retrieved or end-of-file has been reached (there is no functional difference). NCHAR must be set to a non-zero for every successful read that returns data. Used by read options (S), (E), and (G).</td>
</tr>
<tr>
<td><strong>Parameter</strong></td>
<td><strong>Definition</strong></td>
</tr>
<tr>
<td>---------------</td>
<td>---------------</td>
</tr>
<tr>
<td>DDN</td>
<td>Eight-byte character argument, posted by FOCSAM. The value corresponds to the table name for the request. For example, TABLE FILE MYTABLE results in DDN (also known as DDNAME) of MYTABLE, left-justified and blank-padded. Used for all options except (F). Do not modify this parameter. The value is normally used to indicate the desired file to open unless the extended information parameter for filename is available and non-blank.</td>
</tr>
<tr>
<td>ABUF</td>
<td>Pointer, posted by the exit; the pointer is the absolute address of the record obtained and being returned to FOCSAM. Used with all read options (S), (E), and (G). Do not modify this pointer. Instead, modify the location addressed by the pointer.</td>
</tr>
<tr>
<td>RC</td>
<td>Long, return code posted by the exit. Zero indicates no error: non-zero indicates some type of error. Specific non zero values do not activate specific error handlers, there is only one handler and it returns a FOC1143 message. Specific text can be passed back in the extended information RETTEXT parameter so that the generic FOC1143 message and specific text may be displayed. Used with all options.</td>
</tr>
<tr>
<td>KEY</td>
<td>String of 255 bytes posted by FOCSAM, containing the full value of the key for direct or partial keys for generic reads. Not significant for sequential reads. The key value is left justified and limited to 255 bytes. Note that the exit must know the exact key length and its format. For simple cases with a single key, it may suffice to hard-code the value, else information may also be obtained from the extended information parameters. KEY is used with options (E) and (G). Do not modify this parameter.</td>
</tr>
<tr>
<td><strong>Parameter</strong></td>
<td><strong>Definition</strong></td>
</tr>
<tr>
<td>---------------</td>
<td>----------------</td>
</tr>
<tr>
<td>OPT</td>
<td>Four-byte character argument, posted by FOCSAM; the value indicates the type of request. Do not modify this parameter. The options are as follows: &lt;br&gt;<strong>READ OPTIONS</strong> &lt;br&gt;’S’ = Sequential Read. &lt;br&gt;’E’ = Direct Read (EQ). &lt;br&gt;’G’ = Generic Read (GE). &lt;br&gt;<strong>CONTROL OPTIONS</strong> &lt;br&gt;’O’ = OPEN File. &lt;br&gt;’R’ = OPEN Request (position) used for recursive JOINs. &lt;br&gt;’C’ = CLOSE File. &lt;br&gt;’F’ = FIN (FOCUS FIN) - final housekeeping step should be done. &lt;br&gt;These control and read arguments must include three trailing blanks. The standard C header file for the exit (getprv.h) may contain additional references for IBI use only and are not supported for customer purposes.</td>
</tr>
<tr>
<td>* (getprv_info)</td>
<td>Pointer, posted by FOCSAM, pointing to the extended information work area structure (getprv_info). For details, see <em>Work Area Control Block Parameters</em> on page 2813 described below. Do not modify this parameter.</td>
</tr>
</tbody>
</table>

**Note:** The parameters passed to the exit are not delimited by having the high-order bit set on in the last parameter. Make sure that your program does not scan for this high-order bit.

**Reference:**  *Work Area Control Block Parameters*  
The parameter list for the work area control block is an extension of the basic calling parameters. The list includes:

<table>
<thead>
<tr>
<th><strong>Parameter</strong></th>
<th><strong>Definition</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>EYECATCH</td>
<td>An eight-byte string, posted by FOCSAM. The value always contains the literal 'PRIVATE '.</td>
</tr>
</tbody>
</table>
### Calling Parameters and Work Areas

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>PFMCB</td>
<td>Pointer, posted by the exit. The value is generally set during option (O) processing by the exit program and returned unchanged by subsequent FOCSAM calls. This parameter is generally used to point to the dynamic work areas used to maintain reentrancy.</td>
</tr>
<tr>
<td>PFACB</td>
<td>Pointer, posted by the exit. The value is generally set during option (O) processing by the exit program and returned unchanged by subsequent FOCSAM calls for options (C), (R), (E), (G), and (S) and is unique by DDN. This is generally used as a physical file context. This parameter is not valid for option (F).</td>
</tr>
<tr>
<td>PFRPL</td>
<td>Pointer, posted by the exit. The value is generally set during option (R) processing by the exit program and returned unchanged by subsequent FOCSAM calls for options (E), (G), and (S) and is unique for each view within the above PFACB parameter. This is generally used for logical file context. This parameter is not valid for option (F).</td>
</tr>
<tr>
<td>KEYLEN_FIL</td>
<td>Long, posted by FOCSAM. The value is set during option (O) processing by the exit and contains the whole key length for the file.</td>
</tr>
<tr>
<td>KEYLEN_REQ</td>
<td>Long, posted by FOCSAM. The value is set during options (G) and (E) processing by the exit and contains the actual key length for a direct read since it may be less than KEYLENF in a multi-field group key.</td>
</tr>
<tr>
<td>ERRTEXT</td>
<td>Pointer, posted by the exit. The value is the absolute starting address of an error message to be passed back. A FOC1143 and this message are displayed if the RC parameter returned by the exit is non-zero.</td>
</tr>
<tr>
<td>LERRTEXT</td>
<td>Long, posted by the exit. The value must contain the length of the above ERRTEXT message.</td>
</tr>
<tr>
<td><strong>Parameter</strong></td>
<td><strong>Definition</strong></td>
</tr>
<tr>
<td>---------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| INDEX | Full-word binary integer, posted by FOCSAM, based on the Master Files metadata. This option contains the index # by which to access the file.  
0  
Is the primary key in Master File, where ALIAS=KEY or DKEY.  
1, 2, ...  
Are secondary indexes in the Master File, where:  
ALIAS= KEY1, KEY2 through KEYn and INDEX=I  
or  
ALIAS= DKEY1, DKEY2 through DKEYn and INDEX=I |
| RESERVED1 | Pointer, reserved for IBI use. |
| USERID | String of 8 bytes, posted by FOCSAM. The value is the user ID accessing the exit. |
| TRACENUM | Long, posted by the exit. The value must contain the number of lines in the TRACEARR pointer. |
| TRACEARR | Pointer, posted by the exit. The value is the absolute starting address of trace lines to be passed back and inserted into standard trace facilities. |
| RESERVED2, RESERVED3 and RESERVE4D | Set of three pointers, reserved for IBI use. |
| FILENAME | Pointer, posted by FOCSAM. The location of this pointer contains a file name if a FILEDEF or DDNAME has been issued for the table name. For example:  
FILEDEF MYTABLE DISK /home/ralph/myotherdata.ftm  
TABLE FILE MYTABLE  
...  
END  
The pointer contains /home/ralph/myotherdata.ftm, and may be used to as an actual file to open or a flag to indicate a file or a feature. |
### Calling Parameters and Work Areas

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDEXNAM</td>
<td>String of 8 bytes, posted by FOCSAM. The value is the ALIAS of secondary keys when access is via a secondary key. Only one secondary key may access a given request, although the secondary key may be a GROUP consisting of multiple fields.</td>
</tr>
<tr>
<td>RESERVED5 and RESERVED6</td>
<td>Set of two longs, reserved for IBI use.</td>
</tr>
<tr>
<td>RESERVED7</td>
<td>Pointer, reserved for IBI use.</td>
</tr>
</tbody>
</table>

#### Example: Sample C Header File Implementation for Calling and Work Area Control Block Parameters

For your convenience, the following file (getprv.h for SUFFIX=PRIVATE) is provided for inclusion in your C program. It contains both calling and work area control block parameters.

If you choose not to include this file, you are required to write and include your own header file in your C program.

```c
typedef struct getprv_inf_s {
char        eye[8];      /* I: Eye Catcher "PRIVATE " */
void        *pfmcb;      /* O: Pointer to handle for getprv */
          /* Set up by user at first option O */
          /* I: Pointer to handle for getprv */
          /* Passed to user by all other calls */
 void        *pfacb;      /* O: Pointer to handle for file */
          /* Set up by user at option O */
          /* I: Pointer to handle for file */
          /* Passed to user at option C,R,E,G,S */
 void        *pfrpl;      /* O: Pointer to handle for request */
          /* Set up by user at option R */
          /* I: Pointer to handle for request */
          /* Passed to user at option E,G,S */
```
long     keylen_fil;  /* I: Key length (whole) for the file */
          /* Used at option O */
long     keylen_req;  /* I: Key length for the direct read request */
          /* Used at direct read options G,E */
char     *rettext;    /* O: Native db error msg text */
long     lrettext;    /* O: Length of native db error msg text */
long     index;       /* I: Index # by which to access file: */
          /* 0 = Primary Key, (usually as a GROUP=) */
          /* coded in MFD as ALIAS= KEY or DKEY */
          /* 1, 2, ... = Secondary Indexes, */
          /* coded in MFD as ALIAS = KEYn and INDEX=I */
          /* or ALIAS = DKEYn and INDEX=I */

void*    reserved1;  /* IBI Use Only */
char     userid[8];  /* User ID */
long     tracenum;   /* Number of 0 terminated trace lines */
char     *tracearr;   /* Array of trace lines */
void     *reserved2;  /* IBI Use Only */
void*    reserved3;  /* IBI Use Only */
char     *reserved4;  /* IBI Use Only */
char const *filename;   /* Full path name for UNIX, Windows, OpenVMS, OS400 and USS. */

char     indexnam[8]; /* For secondary indexes, ALIAS name from MFD otherwise */
          /* blank. Populated prior to O (Open) option in FOCUS 7.2*/
          /* and up. Field in MFD must have INDEX=I */
long     reserved5;  /* IBI Use Only */
long     reserved6;  /* IBI Use Only */
void     *reserved7;  /* IBI Use Only */
}

typedef void getprv_t (long     *nchar     /* O: Length of data record read */
                        ,char     *ddn       /* I: DDName to read */
                        ,char     **abuf     /* O: Address buffer to return records */
                        ,long     *rc        /* O: Return code. 0 if ok else non 0 */
                        ,char     *key       /* I: Key value for read */
                       )

Adapter Administration for UNIX, Windows, OpenVMS, IBM i, and z/OS 2817
Example: Sample for SUFFIX=PRIVATE (getprv.c)

Although the full sample (which is provided with the product) is too long to include in this document, the included section describes the requirements and steps for building and testing. The actual sample includes extensive annotation to serve as a model.

Ensure that you have the following required sample files.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getprv.c</td>
<td>The sample itself.</td>
</tr>
<tr>
<td>getprv.h</td>
<td>The h file used by the sample.</td>
</tr>
<tr>
<td>getprv.mas</td>
<td>Master file used by test request that call the sample.</td>
</tr>
<tr>
<td>getprv.acx</td>
<td>Access file used by test request that call the sample.</td>
</tr>
<tr>
<td>getprv.ftm</td>
<td>Data file used by test request that call the sample.</td>
</tr>
<tr>
<td>getprv.fex</td>
<td>Focexec test request that calls the table (.mas and .acx) used by the sample.</td>
</tr>
</tbody>
</table>

If you do not already have the Master File, Access File, data or procedure (focexec), the getprv.c file explains how to create them. If you do not already have the getprv.c and getprv.h files contact Customer Support.

Other requirements are access to an installed and configured server, gencpgm (part of server software, and an execution tool such as a server configuration edastart, rdaapp or the Web Console. Note that genpgm must be from a 7.1.1 or higher release, but the programs it generates will work with any 5x or higher server.
Set the EDAHOME environment variable to allow genccpgm to operate properly on the following platforms:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX, USS and OS400</td>
<td><code>export EDAHOME=/home/iadmin/ibi/srv71/home</code></td>
</tr>
<tr>
<td>OpenVMS</td>
<td><code>DEFINE EDAHOME IWAY:[IADMIN.IBI.SRV71.HOME]</code></td>
</tr>
<tr>
<td>Windows</td>
<td><code>set EDAHOME=C:\ibi\srv71\home</code></td>
</tr>
</tbody>
</table>

Using the appropriate platform specific path for genccpgm, build the DLL. For example on UNIX:

```bash
$EDAHOME/bin/genccpgm.sh -m cpgm getprv.c
```

For additional information about genccpgm usage and building DLLs if needed, see the *Stored Procedures Reference*.

- Set the IBICPG environment variable (which tells the Server where to find DLLs) to the name of the directory where the DLLs reside (typically the current directory), using the conventions for the following platforms:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX, USS and OS400</td>
<td><code>export IBICPG='pwd'</code></td>
</tr>
<tr>
<td>OpenVMS</td>
<td><code>DEFINE IBICPG IWAY:[IWAY]</code></td>
</tr>
<tr>
<td>Windows</td>
<td><code>set IBICPG=C:\ibi</code></td>
</tr>
</tbody>
</table>

Alternatively, you can use the EDACONF user directory as the working directory, in which case the DLLs will be picked up automatically.

- Execute the request using edastart -t", "edastart -x" or a front-end tool such as the web console or rdaapp. If exercising via a front-end tool, the DLL must be in the EDACONF user directory or the IBICPG variable must be set before server start up.

To exercise with edastart x use an appropriate platform specific path. For instance:

```bash
/home/iadmin/ibi/srv71/ffs/bin/edastart -x ex getprv
```
After the initial test returns data (Sequential Read), modify the test and add various IF or WHERE statements to observe and exercise the Generic Read (G) and Direct Read (E) behaviors. Note that the sample has a number of printf statements so one can follow behavior of the sample. In a real application these statements would be deleted, commented out, or ifdefed.
Validation for Special Characters and Reserved Words

When creating a synonym, if you choose the Validate check box, the server adjusts special characters and checks for reserved words.

Topics:
- Validation for Special Characters
- Validation for Reserved Words
Validation for Special Characters

If you choose the Validate check box while creating a synonym the following special characters are converted to underscores:

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>dash</td>
<td>%</td>
<td>percent</td>
</tr>
<tr>
<td></td>
<td>space</td>
<td>\</td>
<td>vertical bar</td>
</tr>
<tr>
<td>\</td>
<td>backslash</td>
<td>&amp;</td>
<td>ampersand</td>
</tr>
<tr>
<td>/</td>
<td>forward slash</td>
<td>(</td>
<td>open parenthesis</td>
</tr>
<tr>
<td>,</td>
<td>comma</td>
<td>)</td>
<td>closed parenthesis</td>
</tr>
<tr>
<td>$</td>
<td>dollar sign</td>
<td></td>
<td></td>
</tr>
<tr>
<td>.</td>
<td>period</td>
<td>&lt;</td>
<td>less than</td>
</tr>
<tr>
<td>;</td>
<td>semicolon</td>
<td>&gt;</td>
<td>greater than</td>
</tr>
<tr>
<td>+</td>
<td>plus sign</td>
<td>‘</td>
<td>apostrophe</td>
</tr>
<tr>
<td>*</td>
<td>asterisk</td>
<td>=</td>
<td>equal</td>
</tr>
<tr>
<td>.</td>
<td>period</td>
<td>&quot;</td>
<td>double quote</td>
</tr>
</tbody>
</table>

Validation for Reserved Words

If you choose the Validate check box while creating a synonym reserved words are checked for. The following reserved words cannot be used as names in the created synonym:

<table>
<thead>
<tr>
<th>Reserved Word</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIAS, ALL, ALTER, AND, ANY, AS, ASC, AUTHORIZATION, AVG</td>
</tr>
<tr>
<td>BEGIN, BETWEEN, BINARY, BIT, BOTH, BY</td>
</tr>
<tr>
<td>CALL, CASE, CAST, CHAR, CHARACTER, CHECK, CLOSE, COALESCE, COLFETCH, COMMIT, CONCAT, CONNECT, CORRESPONDING, COUNT, CREATE, CROSS, CURRENT, CURSOR</td>
</tr>
</tbody>
</table>
### Reserved Word

<table>
<thead>
<tr>
<th>Reserved Word</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE, DATE, DATETIME, DAY, DAYS, DEALLOCATE, DEC, DECIMAL, DECLARE, DEFAULT, DELETE, DESC, DISTINCT, DO, DOUBLE, DROP</td>
</tr>
<tr>
<td>ELSE, ELSEIF, END, ESCAPE, EXCEPT, EXECUTE, EXISTS, EXPLAIN</td>
</tr>
<tr>
<td>FETCH, FLOAT, FOR, FOREIGN, FROM, FULL, FUNCTION</td>
</tr>
<tr>
<td>GET, GRANT, GRAPHIC, GROUP</td>
</tr>
<tr>
<td>HAVING, HOUR, HOURS</td>
</tr>
<tr>
<td>IF, IMAGE, INCLUDE, IN, INDEX, INDICATOR, INNER, INOUT, INSERT, INT, INTEGER, INTERSECT, INTO, IS, ITERAT</td>
</tr>
<tr>
<td>JOIN</td>
</tr>
<tr>
<td>KEY</td>
</tr>
<tr>
<td>LEADING, LEAVE, LEFT, LIKE, LOCK, LOGICAL, LONG, LOOP</td>
</tr>
<tr>
<td>MAX, MICROSECOND, MICROSECONDS, MILLISECOND, MILLISECONDS, MIN, MINUTE, MINUTES, MONEY, MONTH, MONTHS</td>
</tr>
<tr>
<td>NATURAL, NOT, NULL, NULLIF, NUMBER, NUMERIC</td>
</tr>
<tr>
<td>OF, ON, ONLY, OPEN, OPTIMIZE, OPTION, OR, ORDER, OUT, OUTER</td>
</tr>
<tr>
<td>PACKAGE, PERCENT, PLAN, PRECISION, PREPARE, PRIMARY, PROCEDURE, PROGRAM, PURGE</td>
</tr>
<tr>
<td>QUERYNO</td>
</tr>
<tr>
<td>RAW, REAL, REFERENCES, REPEAT, RESET, RETURN, RETURNS, REVOKE, RIGHT, ROLLBACK, ROW, ROWS</td>
</tr>
<tr>
<td>SCHEMA, SECOND, SECONDS, SELECT, SERIAL, SET, SMALLFLOAT, SMALLINT, SOME, STOGROUP, SUM, SYNONYM, SYSNAME</td>
</tr>
<tr>
<td>TABLE, TABLESPACE, TEXT, THEN, TIME, TIMESTAMP, TO, TRAILING, TRUNCATE</td>
</tr>
<tr>
<td>UNION, UNIQUE, UNTIL, UPDATE, USER, USER_TYPE_NAME, USING</td>
</tr>
<tr>
<td>VALUES, VARBINARY, VARCHAR, VARGRAPHIC, VARYING, VIEW</td>
</tr>
</tbody>
</table>
### Reserved Word

<table>
<thead>
<tr>
<th>Reserved Word</th>
</tr>
</thead>
<tbody>
<tr>
<td>WHEN, WHERE, WHILE, WITH, WORK</td>
</tr>
<tr>
<td>YEAR, YEARS</td>
</tr>
</tbody>
</table>
